This section describes the potential effects of the alternatives on scenic resources. Although the Proposed Action and alternatives could result in substantial short-term and long-term scenery disturbances associated with the hydroelectric project area, the broader, historic “characteristic landscape” would still remain. Several project features would improve the characteristic landscape’s key features (e.g., historic river segments, canyons and water quality appearance). The following discussion provides specific details on the impacts. The analysis considers the existing scenic character/landscape character, degree of existing disturbance and resulting scenic disturbance resulting from the proposed activity.

3.19.4.3.1 Alternative 1: No Action/No Project

Under the No Action/No Project Alternative, no construction or physical changes would occur; thus, there would be no changes in the short term to the existing scenic quality of the dams, reservoirs, surrounding areas and adjacent river reaches.

*Continued impoundment of water at the Four Facilities could result in water quality impacts that could have long-term impacts on scenic quality. As described in Section 3.2, Water Quality, degradation of water quality could continue in the long term, if the dams are not removed. **The No Action/No Project Alternative would not change this existing condition.***

Not removing the facilities could have the impact that they would remain inconsistent with the VRM classification of the surrounding area (where such inconsistency is defined as a criteria of significance). PacifiCorp’s analysis (2004) identified the following project features as being currently inconsistent with their VRM classification. Under the No Action/No Project Alternative, these features would remain inconsistent with their VRM classification:

- Class II VRM classification—the J.C. Boyle powerhouse and penstocks, J.C. Boyle Dam, bypass canal, and transmission line.
- Class III VRM classification—Copco No. 1 Dam and powerhouse, Copco No. 2 powerhouse and substation, and Iron Gate Hatchery and fish ladder.
- While not identified as being inconsistent with the surrounding area by PacifiCorp’s 2004 analysis, Iron Gate Dam, bypass spillway, powerhouse, penstock, and associated landform and vegetation disturbances are also inconsistent with their Class III VRM classification and would remain so under the No Action/No Project Alternative (personal communication with J. Mosier, Klamath National Forest, April 26, 2011). **The No Action/No Project Alternative would not change this existing condition.**

Ongoing Restoration Actions

Under the No Action/No Project Alternative a number of Ongoing Restoration Actions are currently underway and would be implemented regardless of the Secretarial Determination on the removal of the Four Facilities.

Fish Habitat Restoration Actions

These actions would result in short-term impacts on scenic resources during construction. Ongoing restoration activities for fish habitat would occur throughout the Klamath Basin. These activities may include floodplain rehabilitation, large woody debris replacement, fish passage correction, cattle exclusion fencing, riparian vegetation planting, mechanical thinning of upland areas to mimic natural forest conditions, fire treatment to mimic natural forest conditions, purchase of conservation easements/land, road decommissioning, gravel augmentation, and treatment of fine sediment sources. **During construction, impacts on scenic resources would be potentially significant, albeit temporary. No mitigation measures could be implemented to lessen the impact on scenic resources; therefore it would be significant and unavoidable in the short term.**

These actions could result in long-term impacts on scenic resources. Restoration activities would be anticipated to result in scenery more consistent with the naturally established, characteristic landscape. **Therefore, they have the potential to be beneficial to scenic resources in the long term.**

3.19.4.3.2 Alternative 2: Full Facilities Removal of Four Dams (Proposed Action)

The Proposed Action involves removal of dams and all appurtenant features, with the exception of buried features, at the Four Facilities. The Proposed Action would include reservoir drawdown and removal of four dams. This would expose the former inundated areas to view. After drawdown, the Dam Removal Entity (DRE) would perform restoration activities of the exposed areas. Restoration plans would include stabilizing and revegetating the newly exposed reservoir areas with various herbaceous species through hydroseeding, aerial hydromulching, and planting. Various woody species would also be planted. Invasive and non-native species would be controlled. The hard lines of the dam and large expanses of water in the reservoirs would be changed to a more historic, characteristic scenery displaying natural river canyon landforms with vegetation enframing a continuous river. This scenic change would be visible for a very long distance around the reservoir sites and most reservoir KOPs, and would be permanent. Figures 3.19-3, 3.19-4, and 3.19-5 show aerial photos of the existing reservoirs with an overlay of historic river channels. The historic channel represents what the extent of the Klamath River is expected to be in the long term following removal of the Four Facilities. However, until the restoration is complete, the area would appear barren and/or sparsely vegetated.

In addition, the existing water supply pipeline for the City of Yreka passes under the Iron Gate Reservoir and would be relocated prior to decommissioning to prevent damage from deconstruction activities or increased water velocities once the reservoir has been drawn down. The pipeline would be suspended from a pipe bridge across the river near its current location. Surveys are still required to determine if the bridge is adequate to support the construction traffic from the decommissioning activities. If the existing wooden bridge is not adequate to support the construction traffic, it will be replaced in the same location with a concrete bridge. In addition, the Proposed Action includes removal of existing and construction of new recreation facilities, such as campgrounds and boat ramps, currently located on the reservoir banks down slope to be near the new river bed once the reservoir is removed. Activities described in the KBRA are included in the Proposed Action as connected actions.

Figure 3.19-3 Historic River Channel for J.C. Boyle Reservoir.

Figure 3.19-4 Historic River Channel at Copco I Reservoir.

Figure 3.19-5. Historic River Channel at Iron Gate Reservoir.

The Proposed Action would result in impacts on scenic resources from removal of the Four Facilities. Under existing conditions, some of these facilities do not blend with the natural landscape and can dominate views due to their form, line, color, size or locations, particularly those that appear taller than other natural features from a distance. Since the facilities are inconsistent with the VRM classification for the surrounding area, their removal would result in a landscape that would appear more similar to the surrounding characteristic natural landscape. Figures 3.19-6 and 3.19-7 show photo-simulations of the removal of Iron Gate Dam and Copco 1 Dam, respectively. **Removal of the facilities as part of the Proposed Action would be a beneficial effect.**

The Proposed Action would result in impacts on scenic resources from the removal of some historic properties. Some of the facilities (the Copco 2 facilities shown in Figure 3.19-8, for example) are considered historic properties (FERC 2007), and their removal would require consultation with the Oregon and California State Historic Preservation Office (see Section 3.13, Cultural and Historic Resources). In general, the BLM VRM process is based upon the premise that natural appearing landscapes are more highly valued by the public than modified landscapes. Therefore, the removal of the Four Facilities which would then be replaced by natural landscape would be preferred. However, some historic scenery elements may be considered socially valued and their elimination from the scenic character would be considered a significant scenery impact of the project. **The impact on historic properties would be a permanent significant impact. No mitigation measures could be implemented to lessen the visual impact of the loss of historic properties; therefore it would be significant and unavoidable.**

Figure 3.19-6. Iron Gate Dam before removal (top) and a simulation of what the facility could look like after full removal (bottom) except for Landform/Vegetation restoration details which cannot be fully depicted until completion of the Definite Plan.

Figure 3.19-7 Copco 1 Dam before removal (top) and a simulation of what the facility could look like after full removal (bottom) except for Landform/Vegetation restoration details which cannot be fully depicted until completion of the Definite Plan.

Figure 3.19-8. View of Copco 2 Powerhouse and Historic Structure.

Removal of the Four Facilities could result in short and long-term impacts on scenic resources in formerly inundated reservoir areas. The Proposed Action would include removal of the dams' associated reservoirs, and substantial changes would occur in the former reservoir area during drawdown and until restoration is complete. The Klamath River in the vicinity of the reservoirs would be restored to its historic channel width and depth (see Section 3.6, Flood Hydrology), exposing all previously inundated areas except the historic river channel. The receding water would expose reservoir sediments at the bottom of the reservoir. Since sediment in the reservoirs is less than five feet deep in general, the river channel would not appear to be entrenched or flowing through mud, but rather, would appear very similar to conditions before the river was impounded (with exception of vegetation not yet becoming established). Depending on the sediment, odors may be evident while the reservoir bottoms dry out and new vegetation is established (riverside revegetation planned as part of the project is described below). Erosion of the reservoir sediment and slumping of the sediment is anticipated, followed by drying, cracking, and hardening of the sediment prior to the establishment of vegetation. Existing wetland vegetation on the reservoir shorelines may also die off temporarily, though it may repopulate the newly formed exposed banks (Bureau of Reclamation 2011).

The Proposed Action would involve stabilizing and revegetating the newly exposed reservoir areas with herbaceous and woody vegetation. Until the restoration was complete, however, the area would appear barren and/or sparsely vegetated. The facilities removal schedule estimates that removal of the facilities and appurtenant structures would be completed in stages and would take approximately a year and a half with the objective of revegetation of 75 percent of the reservoir area by desirable vegetation that would provide minor and temporary scenery improvements within three years following dam removal. As discussed, establishment of woody vegetation with cover and density similar to adjacent natural woodlands would take many years to attain. This schedule translates to approximately four and a half years during which the area of analysis would be in a highly visible state of transition, and several more years where contrast from adjacent natural woodlands would be evident. The exposure of previously inundated areas would be considered a moderate contrast from the existing condition because it would dominate the landscape and would encompass a large area surrounding the river. It would likely be visible from various KOPs around each of the reservoirs.

Although revegetation of herbaceous species in barren and/or sparsely vegetated areas may be achieved in the short term (1 to 3 years), it should be noted that this is not necessarily consistent with restoration of natural appearing vegetation patterns below and above the reservoir line. Natural appearing vegetation patterns with woody riparian vegetation may take long term (10 to 50+ years) to develop. Although the condition is considered temporary because the characteristic landscape is expected to be rehabilitated, some adverse scenery impacts would be extensive and long term. In a report prepared for the California State Coastal Conservancy, Philip Williams and Associates, LTD estimated that it will take 30 years for the river corridor habitats to fully recover from the dam removals (Phillip Williams and Associates [PWA] 2009). **The impact on scenic resources would be a significant impact that would occur in both the short and long term, until vegetation has become established. No mitigation measures could be implemented to lessen the impact on scenic resources; therefore it would be significant and unavoidable.**

Deconstruction and restoration activities could result in short-term impacts on scenic resources in the immediate vicinity of the Four Facilities. Removal of the Four Facilities and associated structures would be completed in stages over one year, with primary deconstruction activities occurring over a three-month period. During the deconstruction, the area of analysis would have large construction vehicles and equipment, temporary structures (e.g., trailers, portable toilets, security fencing, temporary power supply, fueling stations), temporary access roads, equipment storage areas, material stockpiles, piles of demolition materials (rock, concrete, steel), and other common construction items that would detract from the natural surroundings. The construction activities would be considered weak to strong contrasts, depending on the amount of vehicles, equipment, and materials in any given area. Some stockpiling areas may be visible but may not stand out in some areas because the color and form of the materials may blend in to the surrounding landscape. However, typically temporary stockpiling of dam fill materials, larger vehicles, and equipment would be a moderate to strong contrast as the color and form would stand out substantially from the existing landscape. Some scenic resources,

such as trees, rocks, and vegetation, particularly in the immediate vicinity of the dams, would need to be removed. Dust emissions from project activities may also temporarily impact views and enjoyment of the river. However, as part of the decommissioning plan, prior to initiation of deconstruction or construction activities, the contractor will be required to prepare and implement a worker Health and Safety Plan prior to the start of construction activities. The Health and Safety Plan will include proper housekeeping and best management practices (BMPs) to keep the construction areas orderly and suppress dust emissions, as required.

During deconstruction, the area would be inconsistent with the VRM classification for the surrounding area. After construction, all vehicles, equipment, and stockpiles would be removed and the area would be restored. **The impact on scenic resources would be significant; this impact would occur temporarily, until deconstruction was complete. No mitigation measures could be implemented to lessen the impact on scenic resources; therefore it would be significant and unavoidable in the short term. As described above, removal of the facilities would benefit scenic resources in the long term through the restoration of the characteristic natural landscape.**

Replacement of the existing wooden Lakeview Bridge just downstream from Iron Gate Dam with a concrete bridge could result in short and long-term impacts on scenic resources. If it is determined that the Lakeview Bridge is not adequate to support the construction traffic from the decommissioning activities, it would be replaced with a concrete bridge in the same location. There would be short-term significant impacts on scenic quality during construction from the presence of construction equipment. Long-term impacts on scenic quality from the change from a wooden to concrete bridge would be less than significant. **The impact on landscape would be a temporary significant and unavoidable impact; however, in the long-term impacts on scenic quality would be less than significant.**

Demolition of existing recreation facilities, such as campgrounds and boat ramps, from the reservoir banks would result in short and long-term impacts on scenic resources. Due to the presence of construction equipment and temporary loss of vegetation, there would be short-term significant impacts on scenic quality during demolition of some of the existing recreation facilities at the reservoirs. In the long term, impacts on scenic quality would be less than significant given implementation of Mitigation Measure REC-1 (the development of a plan to provide similar recreational resources and infrastructure) as well as the revegetation of the drained reservoir lands. **The impact on landscape would be a temporary significant and unavoidable impact; however, in the long-term impacts on scenic quality would be less than significant.**

Deconstruction could create a new source of light or glare that could adversely affect nighttime views in the area. Temporary lighting would be erected for nighttime activities, and security lighting might be required during deconstruction. This light could cause glare that would adversely affect day or nighttime views in the area, particularly for visitors and residents whose homes are near the dam sites, such as the residences near the

Copco Development. **The impact on nighttime views would be a significant impact that would occur temporarily, until deconstruction was complete. Mitigation Measure SQ-1 would reduce this impact to less than significant.**

Drawdown and removal of the four reservoirs could cause temporary changes in the appearance of the Klamath River in the area of the Four Facilities and downstream from Iron Gate Dam. As part of the Proposed Action, the reservoirs would be drawn down, allowing the Klamath River to return to a natural channel depth and width. Hydrologic modeling (see Section 3.6, Flood Hydrology) indicates that the flows in the Klamath River would not be expected to be substantially different from historic conditions after the effects of the initial drawdown passed. Water flow levels are expected to remain very similar to current flow levels and the existing river channel configuration patterns would likely be continued. In the short term, water aesthetics (clarity, turbidity (depth of view), and color) in the receding reservoir and downstream river reaches would likely be affected as the sediment behind the dams erodes and washes downstream (see Section 3.2, Water Quality). In addition to reducing water clarity for a few weeks, the temporary pulse of sediment could also cause possible short term deposition in eddies and slack water pools until subsequent annual flood events move the sediment to the ocean. Depending on the severity of the color change, this would represent a weak to moderate contrast from the existing condition and could be visible from quite a distance, especially from higher elevation viewpoints along the river canyon. **The impact on the appearance of the Klamath River would be a temporary significant impact. No mitigation measures could be implemented to lessen the impact on scenic resources; therefore it would be significant and unavoidable. The impact on scenic resources would be temporary but remain significant and unavoidable.**

Removal of the Four Facilities could result in long-term impacts on scenic resources from changes to water quality. As described in Section 3.2, Water Quality, removal of the dams at the Four Facilities is expected to improve water quality in the long term. The changes are expected to reduce the river's summer algae concentrations, resulting in changes in both water clarity and coloration. An improvement in water quality could result in some improvement in scenic resources, such as water clarity or fish viewing opportunities. These improvements would be most noticeable from on-river and riverside viewpoints, and much less noticeable from river canyon roadway and community viewpoints. **Improvements to water quality would have a beneficial effect on scenic resources.**

Keno Transfer

The Keno Transfer could have adverse effects to scenic quality. The Keno Transfer is a transfer of title for the Keno Facility from PacifiCorp to the DOI. This transfer would not result in the generation of new impacts on scenic quality compared with existing facility operations. Following transfer of title, DOI would operate Keno in compliance with applicable law and would provide water levels upstream of Keno Dam for diversion and canal maintenance consistent with agreements and historic practice (KHSa Section 7.5.4). **Therefore, the transfer of Keno to the DOI would result in no change from existing conditions.**

East and Westside Facilities – Programmatic Measures

The decommissioning of the East and Westside Facilities could have adverse effects on scenic quality. Decommissioning of the East and Westside canals and hydropower facilities of the Link River Dam by PacifiCorp as a part of the KHSAs would eliminate the need to divert water at Link River Dam into the two canals. There would be temporary visual resource effects during facility deconstruction activities. Long-term effects would be dependent on future land use, which is not identified at this time. **Therefore, the decommissioning of the East and Westside Facilities would have a less than significant effect on scenic quality.**

City of Yreka Water Supply Pipeline Relocation – Programmatic Measures

Construction of a new, elevated City of Yreka Water Supply Pipeline and steel pipeline bridge to support the pipe above the river could result in short and long-term impacts on scenic resources. The new prefabricated steel pipe bridge would likely be three spans with a center span of 200 feet and two end spans of 100 feet. The spans would be supported on concrete piers. The new pipeline would be connected to the existing buried pipeline at each end of the bridge. New structures would be painted (or manufactured) to blend with the natural color of the landscape. **The impact on scenic quality would be a significant impact that would occur in both the short and long term.**

Implementation of Mitigation Measure SQ-2, as determined by the Definite Plan, including measures such as coloration, screening from sensitive viewpoints, etc. would reduce impacts on scenic quality; however these impacts could still be significant and unavoidable.

KBRA – Programmatic Measures

The KBRA, which is a connected action to the Proposed Action, includes several programs that could result in impacts on scenic resources, including:

- Phases I and II Fisheries Restoration Plans
- Fisheries Reintroduction and Management
- Fish Entrainment Reduction
- Wood River Wetland Restoration
- Water Diversion Limitations
- On-Project Plan
- Water Use Retirement Program (WURP)
- Interim Flow and Lake Level Programs
- Klamath Tribes Interim Fishing Site
- Power for Water Management Program
- Additional Water Conservation and Storage

Phases I and II Fisheries Restoration Plans

Construction activities associated with the Fisheries Restoration Plan - Phase I and Phase II could result in impacts on scenic resources. The Fisheries Restoration Plan would include measures to restore riparian and floodplain vegetation throughout the Klamath Basin. Actions that could have impacts on scenic resources within the project

area include those where construction or restoration activities would occur, due to the presence of construction equipment and temporary loss of vegetation. These actions include the following:

- Floodplain rehabilitation
- Wetland and aquatic habitat restoration
- Woody debris placement
- Fish passage correction
- Cattle exclusion fencing
- Mechanical thinning and prescribed burning
- Road decommissioning
- Gravel augmentation

These actions would result in temporary impacts on scenic resources within localized construction areas. The restoration actions would not occur in the same location or at the same time as the hydroelectric facility removal actions to contribute to or change potential effects of dam removal on scenic resources. **Therefore, impacts on scenic resources would be less than significant during construction.**

The Fisheries Restoration Plan- Phase I and Phase II could result in long-term impacts on scenic resources. These programs are intended to benefit fish populations and therefore increase fish viewing opportunities, which would result in beneficial effects to scenic resources. In addition, actions are anticipated to result in scenery more consistent with the naturally established, characteristic landscape. These actions would not occur in the same location as hydroelectric facility removal actions and would not affect any scenic improvements as a result of dam removal. **However, they are anticipated to result in beneficial effects to scenic resources.**

Fisheries Reintroduction and Management Plan

Construction activities associated with fish collection facilities would introduce new features into the landscape. Trap and haul operations within the Fisheries Reintroduction and Management Plan would require construction of fish collection and handling facilities below Keno and near Link River Dams to seasonally move fish around Keno Impoundment/Lake Ewauna during times of poor water quality. Constructing these facilities would result in temporary impacts on scenic, and the fish handling facilities would remain in the long term to change the visual landscape. The handling facilities would not be in the same visual area as the Four Facilities; therefore, construction of fish handling facilities would not compound the effects of facility removal actions. **The impacts on scenic resources would be less than significant during construction. However, the impact to scenic resources from the addition of the fish management structures could be a significant, permanent impact. Implementation of Mitigation Measure SQ-2, as determined by the Definite Plan, including measures such as coloration, screening from sensitive viewpoints, etc. would reduce impacts on scenic quality; however these impacts could still be significant and unavoidable.**

Wood River Wetland Restoration

The Wood River Wetland Restoration Project could result in long-term impacts on scenic resources. This project would be a new project designed to provide additional water storage for a total of 16,000 AF of storage in or adjacent to Agency Lake (see Section 2.4.3.8). Depending upon the final outcome of the project design it could provide additional wetland habitat with naturally established, characteristic landscapes beneficial to scenic resources. However, if changes result in more open water storage only (no wetlands), this is not consistent with the naturally established, characteristic landscape.

Open water storage views would be a less than significant impact to scenic resources. Water Diversion Limitations, On-Project Plan, WURP, and Interim Flow, Lake Level Program Power for Water Management Program, and Additional Water Conservation and Storage

Construction activities associated with the WURP could result in impacts on scenic resources. Construction actions would include removal of juniper trees. This could result in temporary impacts on scenic resources within localized areas. Juniper removal actions would be in a different location from the removed Four Facilities, which would reduce the potential for any scenic quality impacts generated by juniper removal actions from contributing to the effects of facility removal. **Therefore, impacts on scenic resources would be less than significant during construction.**

The Water Diversion Limitations, On-Project Plan, WURP, and Interim Flow, Power for Water Management Program, Additional Water Conservation and Storage, and Lake Level Programs could result in long-term impacts on scenic resources. Changes in land uses, including changes from rangeland to water storage areas, could occur under these programs. These actions would not occur at the same location or time as hydroelectric facility removal, which would reduce the potential for any scenic quality impacts generated by these programs from contributing to the effects of facility removal. **These changes have the potential to be beneficial if they result in landscapes (wetlands) that are consistent with the naturally established, characteristic landscape. However, if changes result in more open water storage only (no wetlands), this is not consistent with the naturally established, characteristic landscape and would be a less than significant impact to scenic resources.**

Fish Entrainment Reduction

Construction activities associated with Fish Entrainment Reduction could result in impacts on scenic resources. Construction actions would result in temporary impacts on scenic resources within localized construction areas. Fish entrainment reduction construction actions would not occur at the same location or time as the hydroelectric facility removal actions. As a result, scenic quality impacts generated by these construction actions would not contribute to or change the scenic quality effects of facility removal actions. **Therefore, impacts on scenic resources would be less than significant during construction.**

Fish Entrainment Reduction could result in long-term impacts on scenic resources. This action is anticipated to benefit fish populations and therefore increase fish viewing opportunities, which would result in beneficial effects to scenic resources. However, the entrainment reduction facilities would likely be inconsistent with the naturally established, characteristic landscape, which would be an adverse effect. The installation of fish screens would occur at various existing water diversion structures for the Reclamation's Klamath Project and would not result in a substantial change from existing inconsistencies with natural landscapes. Entrainment reduction facilities would not be near the Four Facilities and would not contribute to or change any scenic quality impacts of facility removal. **Impacts on scenic resources would be less than significant.**

Klamath Tribes Interim Fishing Site

Construction activities associated with the Klamath Tribes Interim Fishing Site could result in impacts on scenic resources. Construction actions would result in temporary impacts on scenic resources within localized construction areas. This construction action would not occur in the same location as the Four Facilities removal actions. As a result, it would not contribute to or change any scenic quality impacts of facility removal.

Impacts on scenic resources would be less than significant during construction. In the long-term changes generated by the presence of the interim fishing site would be anticipated to retain consistency with the naturally established, characteristic landscape and would be a less than significant.

3.19.4.3.3 Alternative 3: Partial Facilities Removal of Four Dams

Under the Partial Facilities Removal of Four Dams Alternative, certain project features would be retained, while providing the requirements for a free-flowing river and for volitional fish passage through all Four Facilities. Table 3.19-2 summarizes which facilities would be retained under the Partial Facilities Removal of Four Dams Alternative.

Figures 3.19-6 and 3.19-7 show photo-simulations of the removal of Iron Gate Dam and Copco 1 Dam, respectively.

The Partial Facilities Removal of Four Dams Alternative could result in impacts on scenic resources from the removal of the Four Facilities and some appurtenant facilities. Impacts on scenic resources would be similar to the Proposed Action. The facilities which remain could continue to be inconsistent with the VRM classification for the surrounding area. Removal of some facilities would result in a landscape that would appear more similar to the surrounding characteristic natural landscape. **Therefore, there would be a beneficial effect on scenic resources. For facilities that stay in place, there would be no change from existing conditions.**

Table 3.19-2. Summary of Features that Would Be Removed under the Proposed Action Alternative and that would be Retained under the Partial Facilities Removal Alternative

Feature	Proposed Action - Full Facilities Removal	Partial Facilities Removal
J.C. Boyle		
- Steel Pipeline and Supports	Remove	Retain
- Powerhouse	Remove	Retain
- Tailrace Channel Area	Remove	Retain
- Power Conveyance Intake	Remove	Retain
- Canal Intake (Screen) Structure	Remove	Retain
- Canal Spillway Channel Area	Remove	Retain
- Tailrace Flume Walls	Remove	Retain

- Switchyard	Remove	Retain
- Tunnel Intake Structure	Remove	Retain
Iron Gate		
- Powerhouse	Remove	Retain
- Fish Hatchery	Retain	Retain

Source: River Design Group. 2010a.

Under the Partial Facilities Removal at Four Dams Alternative the DRE would remove some of the historic properties. (see Section 3.13, Cultural and Historic Resources) In general, buildings are considered visually dominant modifications to the naturally established “characteristic landscape,” however, some facilities could be identified as positive scenery attributes valued for their appearance as historic and cultural features. Therefore, the effects related to the removal of historic properties could be positive, negative, or neutral to scenic resources depending on the historic building. For example, the Copco 2 powerhouse is often perceived as a positive scenery attribute while the J.C Boyle powerhouse is not (compare Figures 3.19-8 with 3.19-9). Under the Partial Facilities Removal at Four Dams Alternative, the J.C. Boyle powerhouse, Copco No. 1 powerhouse, and Copco No. 2 powerhouse would remain as visually dominant modifications to the naturally established “characteristic landscape”. The facilities which remain could continue to be inconsistent with the VRM classification for the surrounding

Figure 3.19-9. View of J.C. Boyle Powerhouse.

area. The condition of the remaining structures could degrade over time, particularly the facilities that would no longer be in use (J.C. Boyle powerhouse and Copco No. 2 powerhouse), and would likely not receive as much maintenance as the facilities still in use. **The impact on historic properties would be a permanent significant impact. No mitigation measures could be implemented to lessen the visual impact of the loss of historic properties; therefore, it would be significant and unavoidable.**

Partial Removal of the Four Facilities could result in short and long term impacts on scenic resources in formerly inundated reservoir areas. The effects would be similar to the Proposed Action. **The impact on scenic quality would be a significant impact that would occur in both the short and long term, until vegetation has become established. No mitigation measures could be implemented to lessen the impact on scenic quality; therefore it would be significant and unavoidable.**

Deconstruction and restoration activities could result in short-term impacts on scenic resources in the immediate vicinity of the Four Facilities. Deconstruction activities would not meet the VRM classification for the surrounding area. **This impact would occur temporarily, until deconstruction was complete. No mitigation measures could be implemented to lessen the impact on scenic quality; therefore it would be significant and unavoidable in the short term.**

Construction of a new, elevated of a City of Yreka water supply pipeline and steel pipeline bridge could result in impacts on scenic quality. The impact on the scenic quality would be the same as the Proposed Action. **It would be a significant impact that would occur in both the short and long term. No mitigation measures could be implemented to lessen the impact on scenic quality; therefore it would be significant and unavoidable.**

Replacement of the existing wooden Lakeview Bridge could result in impacts on scenic quality. The impact on the scenic resources would be the same as the Proposed Action. **The impact on the landscape would be a temporary significant impact; however, the long term impact on scenic quality would be less than significant.**

Relocation of existing recreation facilities could result in impacts on scenic quality. The effects on scenic resources would be the same as for the Proposed Action. **The impact on the landscape would be a temporary significant impact; however, the long term impact on scenic quality would be less than significant.**

Deconstruction could create a new source of light or glare that would adversely affect nighttime views in the area. The effects would be the same as the Proposed Action. **This would be a significant impact that would occur temporarily, until deconstruction was complete. Mitigation Measure SQ-1 would reduce this impact to less than significant.**

Drawdown and removal of the four reservoirs could cause temporary changes in the appearance of the Klamath River in the area of the dams and downstream from Iron Gate Dam. The effects would be the same as those described for the Proposed Action. **The impact on the Klamath River would be a temporary significant impact. No mitigation measures could be implemented to lessen the impact on scenic resources; therefore, the impact on scenic quality would be temporary but significant and unavoidable.**

The Partial Facilities Removal at Four Dams Alternative could result in water quality impacts that could have long-term beneficial effects on scenic resources. The effects would be the same as those described for the Proposed Action. **Restoring the river's water quality would have a beneficial effect on scenic quality.**

Keno Transfer

The effects of the Keno Transfer to visual resources would be the same as under the Proposed Action.

East and Westside Facilities – Programmatic Measures

The effects of East and Westside Facilities decommissioning would be the same as for the Proposed Action.

City of Yreka Water Supply Pipeline Relocation – Programmatic Measures

The effects of the City of Yreka Water Supply Pipeline relocation would be the same as for the Proposed Action.

KBRA – Programmatic Measures

Under the Partial Facilities Removal of Four Dams Alternative, the KBRA would be fully implemented and the effects would be similar to those described for the Proposed Action.

3.19.4.3.4 Alternative 4: Fish Passage at Four Dams

Under the Fish Passage at Four Dams Alternative, no facilities removal (except for demolition of existing fish ladders) would be conducted at the Four Facilities. Fishways would be built at each of the four dams in the form of pool and weir, vertical slot, ice harbor, or hybrid fish ladder with auxiliary water systems.

Continued impoundment at the reservoirs would result in water quality impacts that could have long-term impacts on scenic quality. As described in Section 3.2, Water Quality, water quality conditions would remain the same as the under the No Action Alternative. **There would be no change from the existing condition.**

Continued existence of the Four Facilities could have the impact that some areas would remain inconsistent with the VRM classification of the surrounding area. In general, retained structures and facilities would not benefit scenic quality since they are visually dominant modifications to the naturally established “characteristic landscape”. In addition, under the Fish Passage at Four Dams Alternative, PacifiCorp’s analysis (2004) identified some project features as being currently not consistent with the VRM classification of the surrounding area. Therefore, the areas with these structures would not be able to achieve consistency with the VRM classification of the surrounding area. **There would be no change from the existing condition.**

Demolition, construction, and restoration activities for the fishways could cause short-term adverse effects on the scenic vistas in the immediate vicinity of the Four Facilities. Under the Fish Passage at Four Dams Alternative, selective demolition would be required to accommodate modifications for the fishways and appurtenances. During construction, the area of analysis could have large construction vehicles and equipment, temporary structures (e.g., trailers, portable toilets, security fencing, temporary power supply, and fueling stations), temporary access roads, equipment storage areas, material stockpiles, and other items that would detract from the natural surroundings in terms of scenery, noise, and smells. Bare soil expanses would be visible where temporary roads were constructed, and where excavated soil was moved. Some scenic resources, such as trees, rocks, and vegetation in the work area could be removed. The construction activities would be considered moderate contrasts as the color and form of vehicles and equipment would stand out from the existing landscape but would be unlikely to be visible from great distances. **The impact on scenic resources would be significant; this impact would occur temporarily, until construction was complete. No mitigation measures could be implemented to lessen the impact on scenic quality; therefore it would be significant and unavoidable.**

Construction could create a new source of light or glare that could adversely affect nighttime views in the area. Temporary lighting would be erected for nighttime activities, and security lighting might be required during deconstruction. This light could cause glare that would adversely affect day or nighttime views in the area. This effect could affect visitors and residents whose homes are near the dam sites, such as the residences near the Copco Development. **The impact on nighttime views would be a significant impact that would occur temporarily, until deconstruction was complete, but Mitigation Measure SQ-1 would reduce this impact to less than significant.**

Construction of fishways could cause changes in the appearance of the Klamath River in the area of the Four Facilities and downstream from Iron Gate Dam. No long-term changes to the water levels in the reservoirs and downstream river reaches would be expected with the construction of the fishways. In the short term, water aesthetics (clarity, turbidity (depth of view), and color) in the reservoir and downstream river reaches could be affected by construction in the waterways. It is anticipated that gravity diversions, coffer dams, physical barriers (e.g., sand/gravel bag berms, sheetpiling, concrete blocks), and pumps would be required to isolate and/or dewater work areas for the water intakes and construction of the V-screens within the reservoirs. In addition, nets or screens would be required to prevent aquatic organisms from entering the work area. All of this equipment could cause short-term scenic and water quality impacts while employed. Any change in color from increased sediment would represent a weak contrast from the existing condition because it would likely not be visible for long distances and would occur on a small scale. Additionally, implementation of a Stormwater Pollution Prevention Plan and other measures described in Water Quality would reduce the impacts associated with clarity and color changes. **The impact on the appearance of the Klamath River would be a less than significant, temporary impact.**

Fishways could cause substantial long-term impacts on scenic resources. The addition of the fishways would change the scenic character in the vicinity of the dams by adding hardscape elements that would blend with the facility features but would not blend with the natural landscape and could dominate views due to their size. At Copco 1 and Iron Gate Dams, the fishway structures would be particularly large (see Table 3.19-3) in order to accommodate the vertical drops, which would be 124 feet and 157 feet, respectively. Figures 2-23 (J.C. Boyle), 2-24 (Copco 1), 2-26 (Copco 2), and 2-286 (Iron Gate) from Chapter 2, Proposed Action and Description of the Alternatives, show conceptual layouts for the fishways.

Although the fishways have not yet been designed, they likely could display angular geometry, continuous straight lines, and flat surfaces that may moderately contrast with the colors, forms, and textures of the surrounding characteristic landscape, or may be insignificant compared to scenery impacts of the existing dam facilities. Installation of V-screens at J.C. Boyle, Copco 2 and Iron Gate and a floating surface bypass collector at

Table 3.19-3. Minimum Structure Footprint for Fish Ladders under the Fishway Alternatives

Dam	Minimum Structure Footprint (sq. ft.)
Fishway at Four Dams	
J.C. Boyle	8,712
Copco 1	17,928
Copco 2	3,168
Iron Gate	22,608
Total	52,416
Fishway at Two Dams	
J.C. Boyle	8,712
Copco 2	3,168
Total	11,880

Source: River Design Group 2010b.

Copco 1 would introduce new permanent facilities near the existing intakes visible from the surface of each reservoir but would not be anticipated to dominate the landscape given their relative scale when compared to the dam facilities. Example cast in place pool and weir fish ladders that are proposed for use at the four dams are shown in Figures 3.19-10 and 3.19-11. **The impact to scenic resources from the addition of the fishways could be a significant, permanent impact. Implementation of Mitigation Measure SQ-2, as determined by the Definite Plan, including measures such as Fishway design, coloration, screening from sensitive viewpoints, etc. would reduce impacts on scenic quality; however these impacts could still be significant and unavoidable.**

Trap and Haul – Programmatic Measures

Construction activities associated with fish collection facilities would introduce new features into the landscape. Trap and haul operations would require construction of fish collection and handling facilities at below Keno and near Link River Dams to seasonally move fish around Keno Impoundment/Lake Euwana during times of poor water quality. Constructing these facilities would result in temporary impacts on scenic resources at Keno and Link River Dams, and the fish handling facilities would remain in the long term to change the visual landscape. **The impacts on scenic resources would be less than significant during construction. However, the impact to scenic resources from the addition of the fish management structures could be a significant, permanent impact. The impacts on scenic resources would be less than significant during construction. Implementation of Mitigation Measure SQ-2, as determined by the Definite Plan, including measures such as coloration, screening from sensitive viewpoints, etc. would reduce impacts on scenic quality; however these impacts could still be significant and unavoidable.**

Figure 3.19-10. Example of cast in place pool and weir fish ladder used for fish passage, similar to that proposed for upstream fish passage for all four dams under this alternative.

Figure 3.19-11. Example of fish ladder built into steep bedrock similar to Copco 1 option (photo courtesy of GEI Consultants).

3.19.4.3.5 Alternative 5: Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate

Under the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative, all facilities would be removed at Copco 1 Dam and Iron Gate Dam, and fish passage facilities would be constructed at J.C. Boyle and Copco 2 Dams.

The effects of the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative would be similar to those of the Proposed Action and the Fish Passage at Four Dams Alternative.

*As with the Proposed Action, demolition of Copco 1 and Iron Gate Dams could have long-term scenic effects, including the removal of two dams and reservoirs, and changes from reservoir to river views in the areas near Copco 1 and Iron Gate Dams. **Restoring natural riverine scenery would be a beneficial effect.***

*As with the Fish Passage at Four Dams Alternative, the addition of fishways at the J.C. Boyle and Copco 2 Developments could have long-term impacts on scenic resources. **The impact to scenic resources from the addition of the fishways could be a significant, permanent impact. Implementation of Mitigation Measure SQ-2, as determined by the Definite Plan, including measures such as Fishway design, coloration, screening from sensitive viewpoints, etc. would reduce impacts on scenic quality; however these impacts could still be significant and unavoidable.***

*Temporary deconstruction and construction scenic impacts would be similar to those under the Proposed Action for Copco 1 and Iron Gate Dams sites and could be significant. **No mitigation measures could be implemented to lessen these temporary impacts on scenic quality; therefore they would be significant and unavoidable.***

*Some areas would remain inconsistent with the VRM classification of the surrounding area. The project features that are currently inconsistent with their VRM classification and would remain as visually dominant modifications to the naturally established “characteristic landscape” are: the J.C. Boyle powerhouse and penstocks, J.C. Boyle Dam, bypass canal, and transmission line and Copco No. 2 powerhouse and substation, and the Iron Gate Dam, bypass spillway, powerhouse, penstock, and associated landform and vegetation disturbances. **There would be no change from the existing condition.***

*Lighting impacts would be the same as those under the Proposed Action at the J.C. Boyle and Copco 2 sites and could be significant. **Mitigation measure SQ-1 would reduce this impact to less than significant.***

Trap and Haul – Programmatic Measures

*Construction activities associated with fish collection facilities would introduce new features into the landscape. The trap and haul measures around Keno Impoundment and Lake Euwana would have the same impacts under the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative as the Fish Passage at Four Dams Alternative. **The impacts on scenic resources would be less than significant during***

construction. However, the impact to scenic resources from the addition of the fish management structures could be a significant, permanent impact. Implementation of Mitigation Measure SQ-2, as determined by the Definite Plan, including measures such as coloration, screening from sensitive viewpoints, etc. would reduce impacts on scenic quality; however these impacts could still be significant and unavoidable.

City of Yreka Water Supply Pipeline Relocation – Programmatic Measures

The effects of the City of Yreka Water Supply Pipeline relocation would be the same as for the Proposed Action.

3.19.4.4 Mitigation Measures

The following mitigation measures would reduce the scenic quality impacts associated with the Project.

3.19.4.4.1 Mitigation Measure by Consequences Summary

Mitigation Measure SQ-1 - When practical, as determined by the Definite Plan, scenic quality measures/mitigations (location, design, coloration, screening, etc) shall be identified for all structural, landform and vegetation-altering components of the Project Alternatives. These measures would include one or more of the following: 1) determining the most aesthetically beneficial location and configuration of constructed facilities to reduce visual disturbance; 2) development of scenically harmonious design components into constructed facilities such as edges, borders, and surface textures that blend with surrounding topography and landscape; 3) coloration of constructed facilities, such as colored concrete that mimics as closely as practical the adjacent native soil, bedrock, or vegetation; and 4) screening of constructed facilities, or portions thereof, from sensitive viewpoints through the planting of native riparian or upland vegetation. The application of one or more of these measures, where feasible, will minimize scenery disturbances as needed to either achieve the Project’s Visual Resource Management (VRM) classes, or achieve the most natural appearing scenic quality possible while meeting other Project objectives.

Mitigation Measure SQ-2 - To reduce nighttime light and glare on surrounding residences during construction, the DRE will require the use of reflectors, shields, directional lighting, or other appropriate methods to reduce glare. All lighting will be turned off when not in use and/or motion-controlled lighting will be used, where feasible. Permanent lighting needed for security will be selected to be “dark sky friendly¹” to reduce glare to the surrounding area. “Dark sky friendly” lighting accessories or alternatives to typical lighting systems will be used, where feasible.

¹ <http://www.darksky.org/mc/page.do?sitePageId=118983&orgId=idsa>

3.19.4.4.2 Effectiveness of Mitigation in Reducing Consequences

Implementation of mitigation measure SQ-1 would reduce nighttime light and glare on surrounding residences to less than significant.

Implementation of mitigation measure SQ-2 would reduce Project associated scenery disturbances to the most natural appearing conditions possible and achieve the highest consistency with Project VRM Classes.

Agency Responsible for Mitigation Implementation

The DRE will be responsible for implementing mitigation measures SQ-1 and SQ-2.

Remaining Significant Impacts

The temporary, short-term impacts from deconstruction, construction, and restoration remain significant and unavoidable as no feasible mitigation can reduce all impacts to less than significant. Some long-term changes in scenic resources, including scenery disturbances due to removal of historic facilities, changes from reservoir to river views, and the construction of fishways and fish handling facilities under some alternatives would be significant and unavoidable.

Mitigation Measures Associated with Other Resource Areas

Several other mitigation measures involve construction work, including mitigation measures H-2 (flood-proof structures), GW-1 (deepen or replace affected wells), WRWS-1 (modify or screen affected water intakes), PHS-4 (repair damaged roads), PHS-5 (construct water storage tanks for firefighting), REC-1 (develop new recreational facilities and access to river), TR-6 (assess and improve roads to carry construction loads), and TR-7 (assess and improve bridges to carry construction loads). Construction equipment associated with the mitigation measures would detract from the natural surroundings. The construction activities would be considered weak to moderate contrasts, depending on the amount of vehicles, equipment, and materials in any given area. Effects would be temporary and would not disrupt large expanses of the natural setting. The impact on scenic quality from implementation of mitigation measures listed above would be less than significant.

3.20 Recreation

3.20.1 Area of Analysis

The recreational setting within the Klamath Basin is characterized by an expansive rural landscape that offers a myriad of outdoor recreational opportunities. Within the basin, there are five national forests (Klamath, Fremont, Winema, Six Rivers, and Modoc), one joint national and State park (Redwood), one national park (Crater Lake), two national monuments (Lava Beds and Cascade - Siskiyou) and five National Wildlife Refuges (NWRs) (Klamath Marsh, Tule Lake, Clear Lake, Upper Klamath, and Lower Klamath) that make up the Klamath Basin NWR System. There are 297 miles of Klamath River Wild and Scenic Rivers (WSR) which include segments of the Klamath, Scott and Salmon Rivers and Wooley Creek. These segments are analyzed as those WSR segments most likely to be affected by the proposed alternatives. There are also extensive public and private recreational opportunities along the Klamath River and its reservoirs. Federal and State agencies, including the United States Forest Service (USFS), Bureau of Land Management (BLM) (including the Northern California District, and Lakeview and Medford Districts in Oregon), United States Fish and Wildlife Service (USFWS), the National Park Service (NPS), and California Department of Fish and Game (CDFG), are responsible for managing these lands which are located in Klamath and Jackson Counties, Oregon, and Siskiyou County, California. Figure 3.14-1 in Section 3.14, Land Use, Agriculture and Forest Resources, shows the management of lands in the Klamath Basin. The analysis of potential effects on the Oregon and Klamath WSRs is also included in this section.

The area of analysis includes recreation areas and access along the Klamath River from its headwaters in Oregon to the mouth of the river at the Pacific Ocean. Recreational areas within and directly adjacent to the Klamath Basin are described to provide an overview of regional opportunities. Impacts on recreation opportunities as a result of the alternatives would be limited to those within the Klamath River corridor; therefore, the analysis focuses on those recreational facilities and opportunities adjacent to the Klamath River. Descriptions of recreational opportunities, activities, and settings are presented here by geographic location, including within the Klamath Basin, upstream of J.C. Boyle Reservoir, between J.C. Boyle Reservoir and Iron Gate Dam, and downstream from Iron Gate Dam. Section 3.20.4.3 presents an assessment of potential impacts of the alternatives, including the Proposed Action to remove J.C. Boyle, Copco 1, Copco 2, and Iron Gate Dams (the Four Facilities), on recreational resources.

3.20.2 Regulatory Framework

Recreation within the area of analysis are regulated by several Federal, State, and local policies, which are listed below.

3.20.2.1 Federal Authorities and Regulations

- BLM Redding Resource Management Plan and Record of Decision (1993)
- BLM Klamath Falls Resource Area Resource Management Plan and Rangeland Program Summary and Record of Decision (1995)
- BLM Klamath Falls Record of Decision and Resource Management Plan (2008)
- BLM Medford District Resource Management Plan and Record of Decision (2008)
- Wild and Scenic Rivers Act (WSRA) (16 U.S.C. 1271 et seq.)
- Federal Land Policy and Management Act (43 U.S.C. 1701 et seq.)
- U.S. Forest Service Six Rivers National Forest Land and Resource Management Plan
- U.S. Forest Service Fremont National Forest Land and Resource Management Plan
- U.S. Forest Service Klamath National Forest Land and Resource Management Plan
- National Park Service (NPS) General Management and Strategic Plan, Redwood National Park
- Federal Endangered Species Act (ESA)
- Federal Wild and Scenic Rivers Act, October 2, 1968

3.20.2.2 State Authorities and Regulations

- California Wild and Scenic Rivers Act
- Oregon Parks and Recreation Department, Oregon State Scenic Waterways Act, Klamath River Scenic Waterway Rules

3.20.2.3 Local Authorities and Regulations

- City of Klamath Falls Parks Recreation and Open Space Master Plan

3.20.3 Existing Conditions/Affected Environment

3.20.3.1 Regional Opportunities

Rivers, streams, and lakes are common throughout the mountainous landscape, and grasslands exist in the high plateau areas of the region. A large number of public lands are in the region, including five national forests, five NWRs, one national park, one joint national and State park, and two national monuments. These areas provide sightseeing, camping, hiking, fishing, wildlife viewing, and other recreational opportunities (Figure 3.20-1). In addition, a number of the lands have rivers or river segments designated as WSRs. Table 3.20-1 provides a summary of the opportunities offered on public lands within and adjacent to the Klamath Basin.

3.20.3.1.1 River-Based Recreation

A number of rivers cross the region, including four rivers designated as Wild and Scenic under the WSRA (Sprague River, Sycan River, Smith River, and Trinity River). Portions of the Klamath River (generally described above in Section 3.20.1), are designated as Wild and Scenic under Section 2(a)ii of the WSRA. Other rivers in the Klamath Basin, as shown on Figure 3.20-1 include the Salmon River, Scott River, and Clear Creek. These rivers provide a variety of recreational opportunities, including sightseeing, fishing, and whitewater boating. Figure 3.20-1 shows the location of these rivers relative to the Klamath River. Table 3.20-2 provides a summary of the rivers, the fish species caught,

¹ Information is based on species caught within the 2003-2004 time period.

and the typical types of fishing methods (e.g., boat, bank, fly). Table 3.20-3 summarizes the whitewater boating opportunities in the region. The Oregon WSRs, in particular, have outstanding recreational and/or scenic values along the length of the designated segments. The California WSRs are classified as wild, scenic, and recreational along the length of the designated segments (National Wild and Scenic Rivers 2009).

3.20.3.1.2 Reservoir-Based Recreation

Numerous opportunities for reservoir and lake-based recreation are available in the vicinity of the Proposed Action area. Table 3.20-4 provides a summary of the lakes and reservoirs in the region, including facilities and use levels. Within Klamath County and Jackson County, Oregon and Siskiyou County, California, there are more than 85 boatable lakes, containing nearly 40 boat ramps (Boat Escape Web site 2002). The area also has more than 180 high-elevation and wilderness lakes in Siskiyou County (Federal Energy Regulatory Commission [FERC] 2007). In addition to boat ramps, these lakes provide nearly 2,300 developed campsites within less than a two-hour drive from the subject reservoirs. Some reservoirs in the region are also stocked with trout or warm water fish such as perch or bass. Angling occurs at the many lakes and reservoirs in the region and many are known for having excellent fisheries.

3.20.3.1.3 Federal- and State-Managed National Forests, Public Lands, and Parks Klamath National Forest

The Klamath National Forest consists of about 1.7 million acres, and the 300 miles of rivers within the forest include 202 miles of designated WSR segments (see Section 3.20.3.5). The Klamath River flows for 107 miles through the Klamath National Forest west of Interstate 5 (I-5) to the National Forest's border with the Six Rivers National Forest at Ishi Pishi Falls. The Klamath National Forest provides uncrowded, high quality opportunities for sightseeing, fishing, wildlife viewing, whitewater and flat water boating, hiking and horseback riding along 1,100 miles of trails, hunting, mountain biking, cross-country skiing, off-highway vehicle (OHV) and snowmobile use, mountain

Table 3.20-3. Rivers with Whitewater Boating Opportunities in the Region

River	Generalized Use Levels	Boating Class Type ¹	Miles of Boatable Whitewater	Factors Affecting Use Levels
Clear Creek	Low	III-V	7	Difficult access
Klamath River (above CA/OR State line)	Moderate	III-IV+	31	Remote, not suited for beginner or intermediate boaters, unless accompanied by a commercial outfitter
Klamath River (downstream from Iron Gate Dam)	Moderate	II-V	122	Most skill levels, easy access, 186 miles support multi-day floats, shoreline camping, scenery, many outfitters, commercial use
North Umpqua River	Moderate	II-IV	32	Easy access, most skill levels, scenery, boatable year round, shoreline suitable for camping
McCloud River	Moderate	II-IV	35	Proximity to I-5, most skill levels, low flows in summer
Pit River	Low	IV-V	34	Fragmented/short runs with long stretches of flat water between, remote location
Rogue River	High	II-V	100+	Easy access, most skill levels, scenery, boatable year round, shoreline suitable for camping, many commercial outfitters
Salmon River	Moderate	II-V	44	Requires advanced/expert boating skills, commercial use
Scott River	Low	III-V	20	Recommended for expert boaters only
Smith River	Low	II-V	100+	Requires advanced/expert boating skills, low summer flows
Upper Sacramento River	Low	III-V	36	Proximity to I-5, average solitude
Trinity River	Moderate	II-V	100+	Most skill levels, easy access, commercial use

¹ As rated by the American Whitewater International Scale of Difficulty (American Whitewater 1998).

climbing, and spelunking. There are 34 developed campgrounds within the forest, and dispersed day and overnight use occurs in various locations throughout the forest (FERC 2007; U.S. Department of Agriculture [USDA] 2010).

Six Rivers National Forest

The Six Rivers National Forest encompasses more than 1 million acres of land located east of the redwood belt of northwestern California and the Hoopa Valley and Yurok Indian Reservations, extending from the Oregon border south through Del Norte, Siskiyou, Humboldt, and Trinity Counties. The Klamath River runs for 20 miles through the Six Rivers National Forest from west of Ishi Pishi Falls to the boundary of Hoopa Tribal lands. Recreational opportunities in the Six Rivers National Forest include 24 developed campgrounds, 400 miles of trails for hiking and sightseeing along 365 miles of designated WSRs, backpacking, whitewater boating on 100 miles of the Smith River and approximately 50 miles of the Trinity River, world-class salmon and

steelhead fishing and hunting opportunities. The Six Rivers National Forest is also home to many rare and endangered plants and flowers that are attractive for botanical tours (USDA 2009).

Redwood National and State Parks

Redwood National Park is one of four park units jointly managed as Redwood National and State Parks under a cooperative management agreement between the NPS and the California Department of Parks and Recreation (California State Parks). Together with three State parks-Prairie Creek Redwoods, Del Norte Coast Redwoods, and Jedediah Smith Redwoods State Parks-the parks encompass 133,000 acres. These parks preserve the largest remaining sections of ancient coast redwood forest, including some of the world's tallest and oldest trees and provide forest and stream habitat for threatened and endangered birds and salmonids (NPS 2005). Recreational opportunities include four developed campgrounds, hiking, backpacking, horseback riding, scenic drives, visitor centers, and ranger-led programs designed to inform and inspire the public on this unique ecosystem (NPS 2009).

Fremont-Winema National Forest

The Fremont-Winema National Forest is located in south-central Oregon on the eastern slopes of the Cascade Mountain range. The combined forest area consists of 2.3 million acres. The lowest elevations of the forest adjoin Upper Klamath Lake where there are marshes, lakes, forested slopes, and wide basins. There are 22 developed campgrounds and 9 day-use areas across the forest. Recreational opportunities include sightseeing, fishing, wildlife viewing, hiking, downhill skiing, and hang gliding (FERC 2007).

Modoc National Forest

The Modoc National Forest is located along the California-Oregon State Line and is the most northeasterly of the national forest units in the Pacific Southwest Region. The forest consists of approximately 2 million acres. The Modoc National Forest does not draw as large a volume of recreational travel compared to other forests closer to population centers, with the exception of the one-month open deer season which is known to attract as many as 10,000 hunters. Other recreational opportunities include fishing, camping, hiking, and sightseeing (USFS 2011).

BLM Klamath Falls Resource Area

Located in the BLM Lakeview District, the public lands administered by the Klamath Falls Resource Area are in southern Klamath County on the eastern slope of the Cascade Range. In addition to BLM-administered land (212,000 acres), there are 21,000 acres of non-federally owned surface land underlain by subsurface Federal mineral estate within the Resource Area that are also administered by the BLM (BLM 1995). The two main recreation areas located in the Klamath Falls Resource Area include the Klamath WSR and the Wood River Wetland (BLM 2011). The Klamath WSR area is located 30 miles southwest of Klamath Falls. While travel is limited to rough gravel roads and jeep trails, the area is utilized for wildlife viewing, hunting, fishing, biking, hiking, and camping, among other recreational activities (BLM 2011). The Klamath Falls Resource Area Management Plans (BLM 1995 and 2008) list 15 developed and semi-developed

recreation sites including day-use and campsites, and four developed trails. The Wood River Wetland area is open to the public year-round for day-use only, and includes paved parking, a trail, a canoe launch, picnic areas, toilets, and interpretive signs (BLM 2011).

Recreational activities that take place at the Wood River Wetland area include wildlife viewing, botanical sightseeing, hunting, fishing, canoeing, hiking, and biking (BLM 2011).

Cascade-Siskiyou National Monument

Located in the BLM Medford District, the Cascade-Siskiyou National Monument was designated a national monument by presidential proclamation in 2000. The national monument is located where the Cascade, Klamath and Siskiyou mountain ranges converge and consists of 54,000 acres of BLM-administered lands (BLM 2011). The area is recognized for its remarkable biological diversity and varied landscape, as well as important archaeological and historical resources. The Hyatt Lake Recreational Area is the only developed recreational site within the monument and includes many developed campgrounds (BLM 2008). The major recreational activities within the monument include camping, hiking, horseback riding, sightseeing, hunting, fishing, cross-country skiing, snowmobiling, rock climbing, and nature study (BLM 2008). The majority of the monument is undeveloped and visitor use is estimated as light to moderate throughout. The Hyatt Lake Recreational Area receives moderate use during April through October. In 2003, records show that over 14,000 people visited the recreational area (BLM 2008).

3.20.3.2 Recreation Opportunities along the Klamath River Segment Upstream of J.C. Boyle Reservoir

3.20.3.2.1 Recreation Facilities and Opportunities

Upstream of J.C. Boyle Reservoir, a small number of developed recreation facilities exist. The following paragraphs provide brief descriptions of each facility and the recreational opportunities available.

Agency Lake is connected to the northern arm of Upper Klamath Lake. Although Agency Lake has no marina, there are two public boat launches and it has a fishery that features trophy redband trout. Other popular recreational activities at the lake are sightseeing, including wildlife viewing of waterfowl, otter, mink, deer, and bald eagles (and waterfowl hunting) (Southern Oregon Directory and Guide 2010). The BLM's Wood River Wetland Management Area is on Agency Lake. As shown in Table 3.20-4, a number of campgrounds surround the lake.

Upper Klamath Lake is the largest freshwater body of water in Oregon. In the northern portion of the lake, Pelican Bay is known for its population of redband trout and is an extremely popular destination for fly-fishing. The bay is also a popular location for canoeing and kayaking, as well as sightseeing and wildlife viewing. Other popular

activities in Upper Klamath Lake include sailing and waterfowl hunting. As shown in Table 3.20-4 above, there are numerous campgrounds and boat launches surrounding the lake.

The Link River segment of the Klamath River, an approximately 1-mile stretch downstream from Link River Dam, has only one developed recreational facility, the Link River Nature Trail. This 1.4-mile trail is for pedestrian use only and follows a gated access road on the west side of the Link River Bypass Reach. The Link River Nature Trail is popular for sightseeing, hiking, walking, jogging, trout fishing, and bird watching (FERC 2007).

The Keno Impoundment/Lake Ewuana provides various recreational opportunities, including fishing, picnicking, boating, camping, sightseeing, and wildlife viewing. In the fall, waterfowl hunting is a popular activity at Keno Impoundment/Lake Ewuana. Although most of the land adjacent to the reservoir is privately owned, Lake Ewauna has several public access areas, including the City of Klamath Falls Veterans’ Memorial Park/Boat Launch, Miller Island Boat Launch, the Klamath Wildlife Viewing Area, and the Keno Recreation Area and Campground (PacifiCorp 2004). Table 3.20-5 provides a summary of the facilities and estimated annual visitation and capacity as assessed by PacifiCorp as part of relicensing studies for the Klamath Hydroelectric Project (KHP) (PacifiCorp 2004).

Table 3.20-5. Keno Impoundment/Lake Ewauna Developed Recreation Facilities

Site Name	Facilities	2001/2002 Est. Annual Use (Recreation Days ^{1,2})	Est. Facility Use vs. Capacity
Klamath Falls Veterans’ Memorial Park/Boat Launch	Boat launch, day use area	42,500	Exceeding capacity
Miller Island Boat Launch and Klamath Wildlife Viewing Area	Boat launch, wildlife viewing trail, and a portable toilet	7,300	Approaching capacity
Keno Recreation Area and Campground	Campsites (26), day use area, restrooms, boat launch and boarding dock	6,000	Below capacity

Source: PacifiCorp 2004; FERC 2007.

Notes:

¹ Recreation days are defined as one visitor to a recreation area for any reason in a 24-hour period.

² Data for PacifiCorp Reservoir use was collected by PacifiCorp in 2001 and 2002. No more recently collected data exists or is available.

The Klamath Falls Veterans’ Memorial Park provides a boathouse and boat launch ramp on the northern shoreline of Keno Impoundment/Lake Ewuana and is managed by the City of Klamath Falls, Department of Parks and Recreation. Along the northwestern end of the lake, the Klamath Wingwatchers Lake Ewauna Nature Trail provides opportunities

for bird watching and hiking. This 1.8-mile trail connects Veterans' Memorial Park to the Link River trail, along the Link River to the north. Another trail is currently under construction on the northeastern side of the lake (Klamath Birding Trails 2010).

The Miller Island Boat Launch is on the east shore of Keno Impoundment/Lake Ewuana about 6 miles south of Klamath Falls, and is managed by the Oregon Department of Fish and Wildlife. The facility is accessed by Miller Island Road, which runs three miles through the Klamath Wildlife Area and Miller Unit, which provides an entrance station area, parking area, wildlife viewing trail, and a portable toilet. The Keno Recreation Area and Campground on the southwestern shore of the Keno Impoundment/Lake Ewuana provides a campground, day use area, and boat launch. The campground has 26 developed campsites, restrooms, and a recreational vehicle (RV) dump station. Recreational opportunities in this area include camping, fishing, picnicking, sightseeing, and boating. The Keno Recreation Area consists of upper and lower use areas, with the upper area adjacent to the campground and the lower area adjacent to the boat launch (FERC 2007).

3.20.3.2.2 Whitewater Boating Opportunities

The Klamath River downstream from Link River Dam provides approximately one mile of river suitable for whitewater boating and other river-based activities. Recreational studies of this reach have not detected whitewater boating use; however, there are anecdotal accounts of boating use occurring in the reach (FERC 2007). There is one short Class III/IV rapid and one Class II/III ledge drop in this segment of the river.

The Klamath River downstream from Keno Dam provides approximately five miles of river suitable for whitewater boating, although not much boating use is reported for this reach, perhaps due to its level of access and short run length, including a flat water paddle above J.C. Boyle. The reach is rated Class III difficulty, and flows acceptable for whitewater boating opportunities range from 1,000 to 4,000 cubic feet per section (cfs). Table 3.20-6 provides a summary of acceptable flow ranges for whitewater boating and other flow-dependent recreational activities in the Klamath River (from the Keno Reach to the ocean).

Fishing Opportunities

Fishing is allowed from September 30 until June 16 on the Klamath River downstream from Link River Dam. The highest use in this area occurs from late winter through spring; this area is mainly used by City of Klamath Falls local residents. At lower flow times, anglers use the river at a few sites where there is access for bank fishing through thick riparian vegetation. Catch records indicate that although angler success is consistently low, there is a greater percentage of larger fish caught in this reach than between J.C. Boyle Dam and the State line. Table 3.20-6 below summarizes flows acceptable for fishing opportunities in the various reaches of the Klamath River.

Table 3.20-6. Acceptable Flow Ranges for Various River-Based Activities for Reaches of the Klamath River

River Reach (Length of Reach)	Activity	Low Value (cfs) ¹	High Value (cfs) ¹
Keno Reach (5.0 miles)	Whitewater Boating – Standard	1,000	4,000
	Play Boating	1,100	1,800
	Fishing	200	1,500
J.C. Boyle Bypass Reach (4.3 miles)	Whitewater Boating – Standard	1,300	1,800
	Fishing	200	1,000
Hell's Corner Reach (16.4 miles)	Whitewater Boating/Kayaking ²	1,000	3,500
	Whitewater Boating/Commercial Rafting ²	1,300	3,500
	Fishing ³	200	1,500
Copco 2 Bypass Reach (1.3 miles)	Whitewater Boating	600	1,500
	Fishing	50	600
Iron Gate to Scott River (47 miles)	Whitewater Boating/Fishing	800	4,000
Scott River to Salmon River (76 miles)	Boating	800	7,000
	Fishing	800	4,000
Salmon River to Trinity River (23.1 miles)	Whitewater Boating/Fishing	800	10,000
Trinity River to Ocean (43.4 miles)	Whitewater Boating/Fishing	1,800	18,000

Notes:

¹ Values were determined by the recreation sub-team (2010) from relicensing documents (PacifiCorp 2004; FERC 2007) and consultation with USFS and BLM representatives.

² Flows are within the desirable range during the daily peak hydroelectric operations period (between 10:00 AM and 2:00 PM).

³ Flows are within the desirable range for at least 4 hours during the daily non-peak hydroelectric operations period (either between 5 AM and 11 AM or between 3 PM and 9 PM).

Key:

cfs: cubic feet per second

3.20.3.3 Recreation Opportunities in the Klamath River Segment Between J.C. Boyle Reservoir and Iron Gate Dam

3.20.3.3.1 Recreation Facilities and Opportunities

The subject dams impound four water bodies on the Klamath River: J.C. Boyle, Copco 1, Copco 2, and Iron Gate Reservoirs. In addition to these reservoirs, there is a stretch of unimpounded river between J.C. Boyle Reservoir and Copco Reservoir.

Figures 3.20-2(a), (b), and (c) show the locations of these reservoirs, and the following sections describe recreational opportunities at each of these areas.

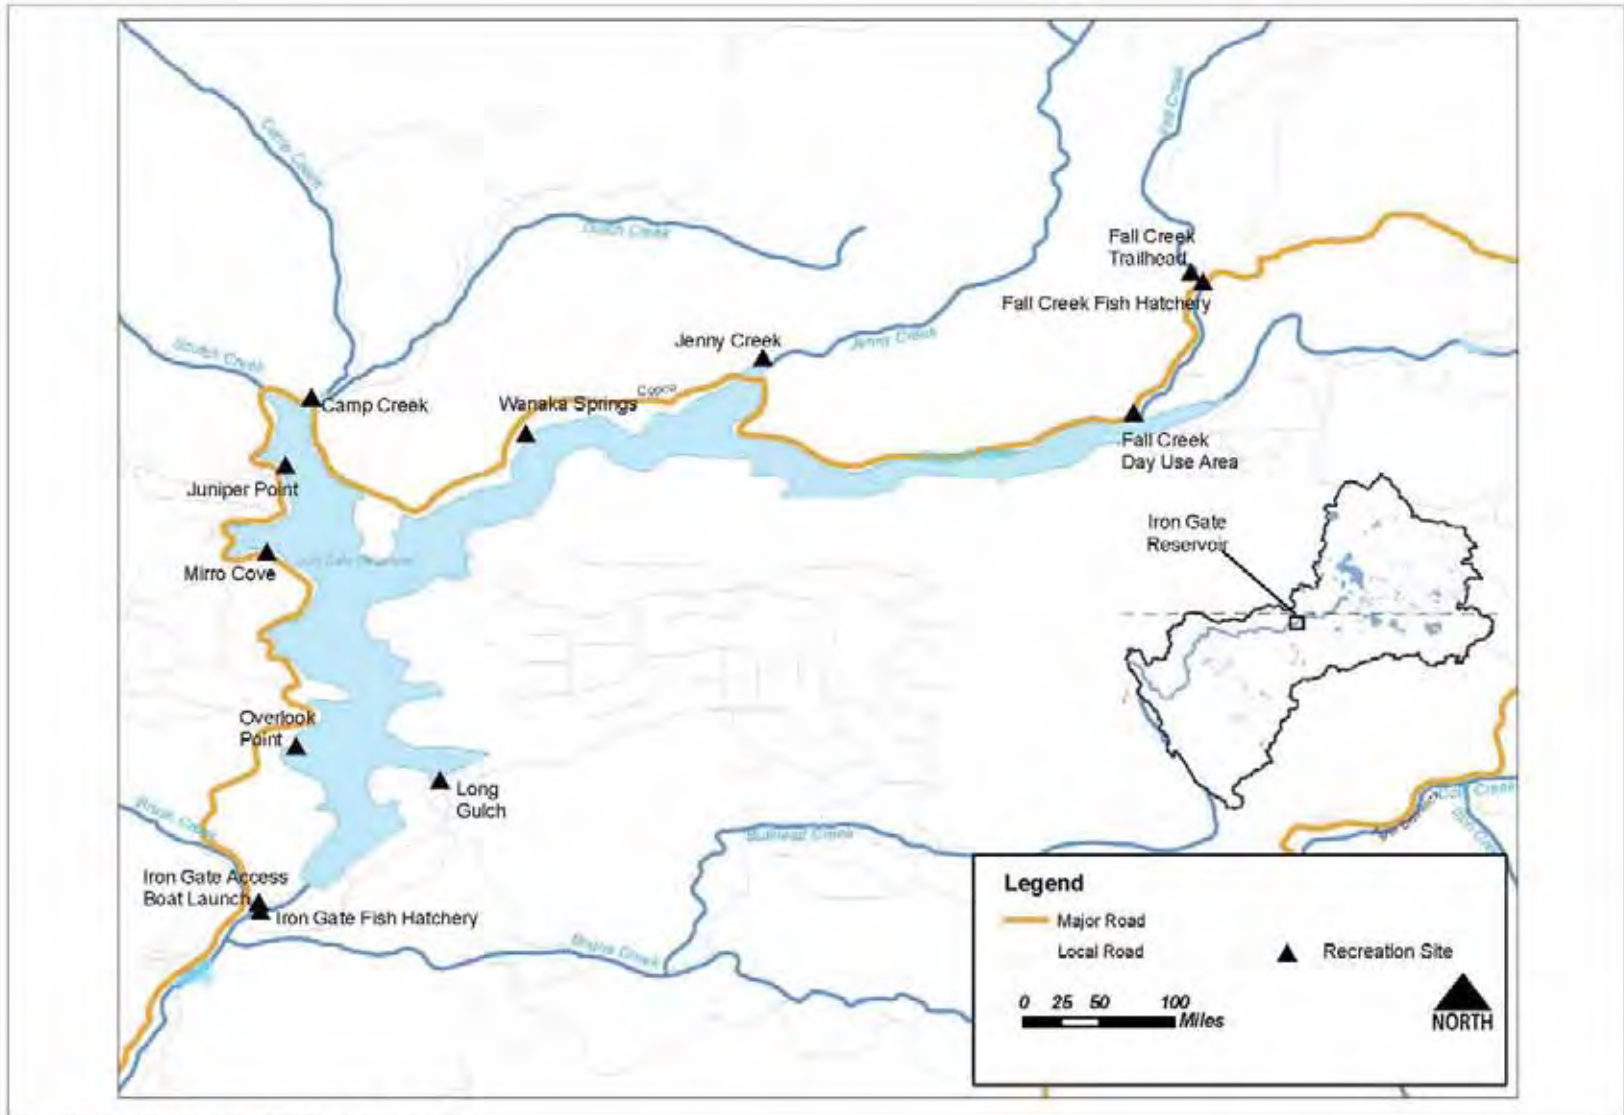

Figure 3.20-2a. Iron Gate Recreation Areas.

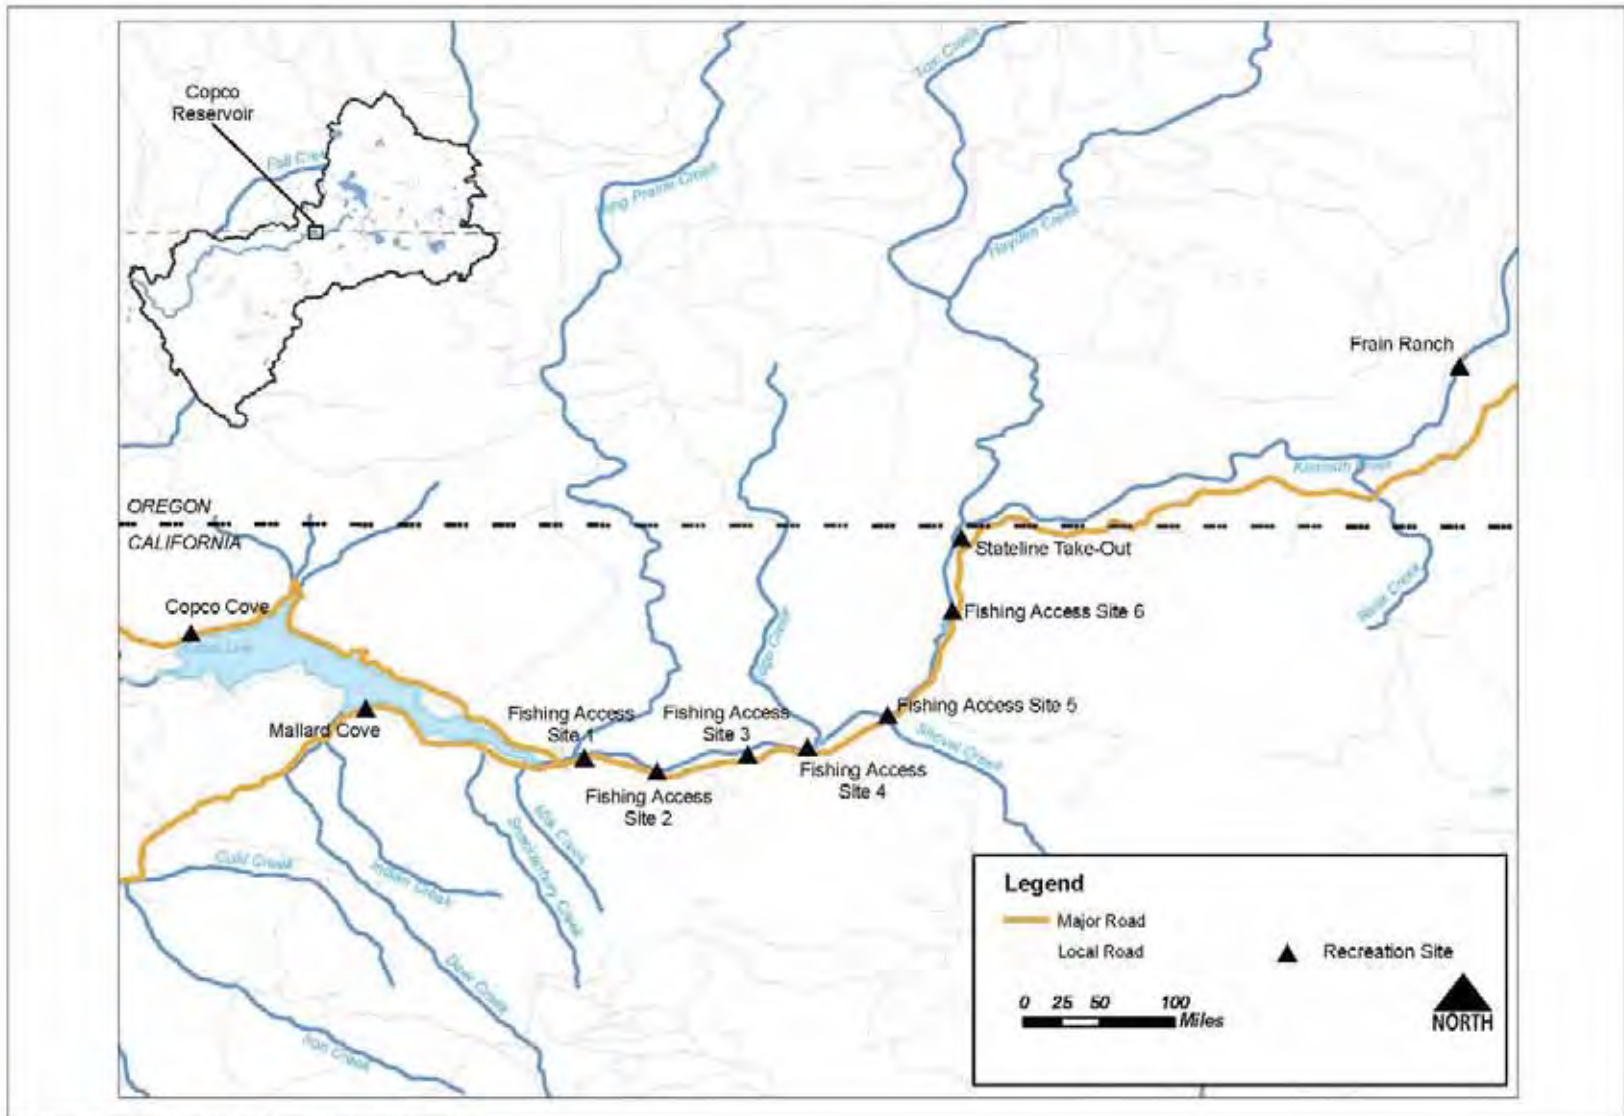

Figure 3.20-2b. Copco Recreation Areas.

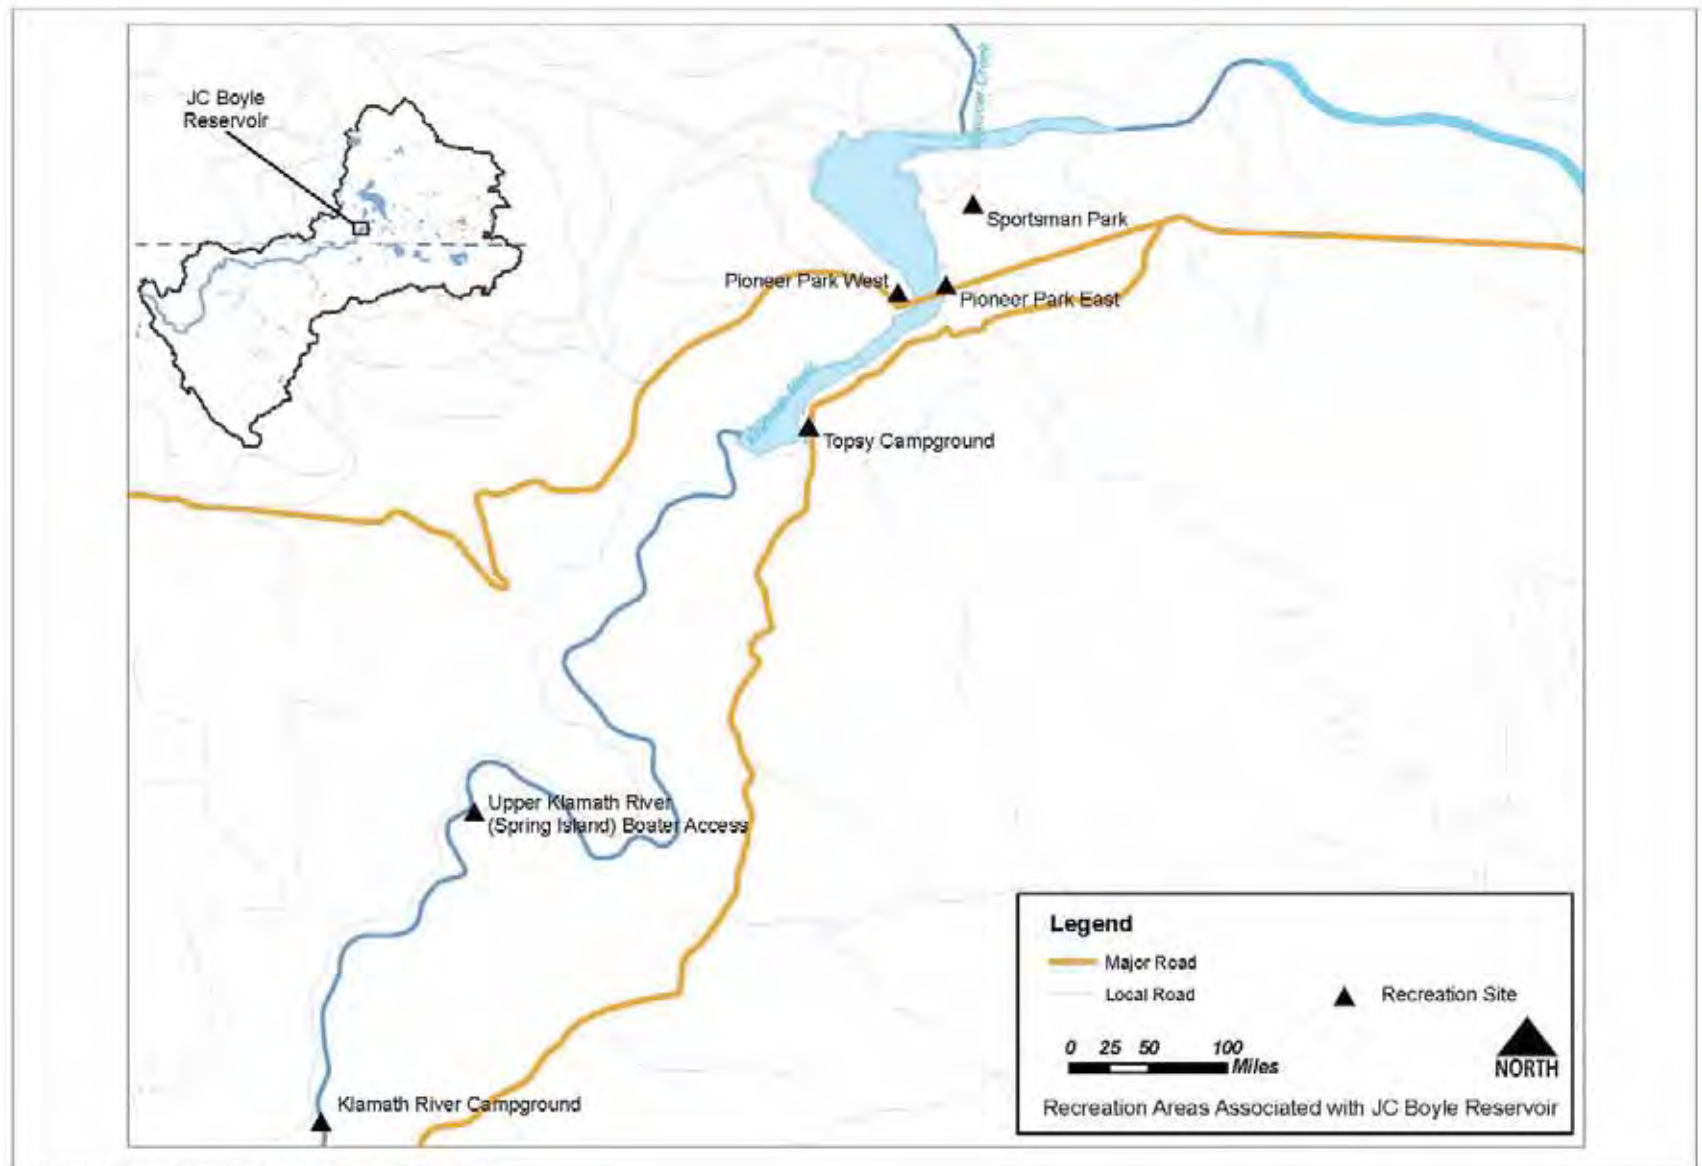

Figure 3.20-2c. J.C. Boyle Recreation Areas.

J.C. Boyle Reservoir

J.C. Boyle Reservoir encompasses about 420 surface acres and is about 3.6 miles long. Developed public recreational facilities at the reservoir include Pioneer Park, Sportsman’s Park, and Topsy Campground (Table 3.20-7).

Table 3.20-7. J.C. Boyle Reservoir Developed Recreation Facilities

Site Name	Ownership	Facilities	2001/2002 Est. Annual Use	Est. Facility Use vs. Capacity
Pioneer Park	PacifiCorp	Picnic areas, boat launches, interpretive signs, restrooms	16,700	Below capacity
Topsy Campground	BLM	Campsites (16), an RV dump, two day use areas, a boat launch with boarding dock, an accessible fishing pier, restrooms	5,600	Below capacity
Sportsman’s Park	Klamath County	Shooting ranges, dirt racetracks, archery courses, a model aircraft flying field, OHV area, restrooms	12,600	Below capacity

Source: PacifiCorp 2004; FERC 2007.

Pioneer Park is owned and operated by PacifiCorp and it lies off Oregon State Highway 66 (State Highway 66) east and west of Spencer Bridge. Pioneer Park is a day use area that provides picnic areas, boat launches, interpretive signs, and two restroom facilities. It has an improved boat ramp on the east shore just off State Highway 66, and a picnic area and unimproved boat launch on the west shore. Popular activities at this location include sightseeing, boating, fishing, swimming, and picnicking (PacifiCorp 2004).

Topsy Campground is managed by the BLM. The campground is south of State Highway 66 off Topsy Grade Road, a gravel road maintained on an as-needed basis by BLM, private owners, timber companies, and PacifiCorp. This site features a campground with 16 sites, an RV dump, two day use areas, a boat launch with boarding dock, an accessible fishing pier, and two restroom facilities. The campground is available to the public and BLM charges fees for day use and camping at this facility (PacifiCorp 2004).

Sportsman’s Park, approximately 0.25 mile east of the reservoir, is a multi-use recreation area owned by Klamath County and leased long term to Klamath Sportsman’s Park Association. The facility does not provide developed reservoir access, but does provide river access for fishing. The park contains shooting ranges, dirt racetracks, archery courses, and a model aircraft flying field. The park also has facilities for self-contained RVs and some tent camping. Annual membership passes and single-day passes for use of the park are available to the general public for a fee (PacifiCorp 2004; Klamath Sportsman’s Park 2010).

Hell's Corner Reach

The Hell's Corner Reach of the Klamath River from J.C. Boyle Reservoir to Copco Reservoir extends about 16.4 river miles. Several public fishing and boat access areas exist along this reach, as summarized in Table 3.20-8.

Table 3.20-8. Hell's Corner Reach Developed Recreation Facilities

Site Name	Facilities	2001/2002 Est. Annual Use (Recreation days)	Est. Facility Use vs. Capacity
Spring Island Boater Access	Launch area, shoreline fishing access, restrooms	5,200	Below capacity
Klamath River Campground	Campsites (3), shoreline fishing and boating access, restrooms	1,000	Below capacity
Stateline Take-out	Boat put- in/take-out, shoreline fishing access, restrooms	2,700	Approaching capacity
Fishing Access Sites 1-6	Shoreline fishing access, parking	3,600	Below capacity

Source: PacifiCorp 2004; FERC 2007.

The Spring Island boater access is adjacent to (downstream from) the J.C. Boyle Powerhouse and is managed by BLM. This site provides car-top whitewater boat launching and shoreline fishing access. The Klamath River Campground, managed by BLM, is about three miles downstream from the J.C. Boyle Powerhouse. The campground has three developed campsites and the shoreline which can be used for fishing and boater access. The State line take-out access area, at the Oregon/California State line, includes upper and lower areas and is co-managed by BLM and PacifiCorp. The facility provides shoreline fishing and boat launching access. The fishing access sites provide access to the Klamath River in six locations between the State line take-out access area and Copco Reservoir.

Copco 1 Reservoir

Copco 1 Reservoir, which covers about 1,000 water surface acres and is about 4.5 miles long, has two publicly available day use facilities: Mallard Cove and Copco Cove that are owned and operated by PacifiCorp. These facilities provide day use access, and although they are not official campgrounds, camping occasionally occurs at both locations. Table 3.20-9 summarizes the facilities and estimated use during 2001/2002 at both of these areas.

Table 3.20-9. Copco 1 Reservoir Developed Recreation Facilities

Site Name	Facilities	2001/2002 Est. Annual Use ¹	Est. Facility Use vs. Capacity
Mallard Cove	Picnic area, restrooms, boat launch with boarding dock	7,600	Below capacity
Copco Cove	Picnic area, restrooms, boat launch with boarding dock	1,250	Below capacity

Source: PacifiCorp 2004; FERC 2007.

Note:

¹ Recreation days are defined as one visitor to a recreation area for any reason in a 24-hour period. Estimated use was during the 2001/2002 study period (PacifiCorp 2004).

Mallard Cove, on the south shore of Copco Reservoir, is accessed off Ager-Beswick Road and includes day use facilities, two restrooms, and a boat launch with boarding dock. Copco Cove, on the western shoreline of Copco Reservoir, off of Copco Road, has a small picnic area, two restrooms, and a boat launch with boarding dock (PacifiCorp 2004).

Copco 2 Reservoir

Copco 2 Reservoir is relatively small (approximately 40 water surface acres and about 0.3 mile long) and has a narrow configuration with steep and difficult shoreline access. Copco 2 Reservoir has no recreation facilities and no public access (FERC 2007).

Iron Gate Reservoir

Iron Gate Reservoir is approximately 944 water surface acres and 6.8 miles long. The reservoir has the highest concentration of recreation sites of all the developments associated with the PacifiCorp facilities. The developed facilities at Iron Gate Reservoir are owned and managed by PacifiCorp and include a trail (Fall Creek Trail), five combination day use and campground areas (Jenny Creek, Camp Creek, Juniper Point, Mirror Cove, and Long Gulch), three day use areas (Fall Creek, Overlook Point, and Wanaka Springs), and a fish hatchery and associated day use area (Iron Gate). Recreational opportunities include sightseeing, swimming, fishing, boating, and day and overnight use. Summer and weekend use is quite high at the reservoir, due to the popularity of bass tournaments, waterskiing, and camping. Table 3.20-10 summarizes the facilities at these sites and PacifiCorp’s estimated annual recreation visitation and capacity during the 2001/2002 study period.

The Fall Creek Day Use Area is at the upper end of the reservoir and includes a picnic area, boat launch access, and restroom facilities. This small day use area is adjacent to the CDFG Fall Creek Fish Hatchery and provides access to Fall Creek Trail. Fall Creek Trail is a short (0.1 mile) trail located adjacent to the Fall Creek Fish Hatchery where visitors can hike up to Fall Creek Falls.

Wanaka Springs Day-Use Area provides picnic areas, a fishing dock, and restroom facilities, and some informal camping occurs in the area.

Table 3.20-10. Iron Gate Reservoir Developed Recreation Facilities

Site Name	Facilities	2001/2002 Est. Annual Use (Recreation days)	Est. Facility Use vs. Capacity
Fall Creek Day Use Area and Fall Creek Trail	Picnic area, boat launch access, restrooms, hiking trail	4,150	Below capacity
Overlook Point	Restrooms	1,900	Below capacity
Wanaka Springs Day Use Area	Fishing dock, restrooms	4,150	Exceeding capacity
Jenny Creek Day Use Area and Campground	Campsites (6), restrooms	3,700	Approaching capacity
Camp Creek Day Use Area and Campground	Campsites (13), boat launch, boarding and fishing docks, swimming area, a RV dump station, sports field, interpretive display restrooms	15,250	Exceeding capacity
Juniper Point Day Use Area and Campground	Campsites (9), a fishing dock, restrooms	4,700	Exceeding capacity
Mirror Cove Day Use Area and Campground	Campsites (10), a boat launch, restroom	11,140	Exceeding capacity
Long Gulch Day Use Area and Campground	Picnic sites, boat launch, restrooms	5,200	Below capacity
Iron Gate Fish Hatchery	Picnic area, picnic shelter, visitor center/interpretive kiosk, restrooms, trail to river	2,200	Below capacity

Sources: PacifiCorp 2004; FERC 2007.

Overlook Point is on the west side of the reservoir, approximately 0.75 mile upstream of the dam. The facility has picnic sites on moderately steep topography, providing a good view of the reservoir and surrounding landscape.

Jenny Creek Day Use Area and Campground includes six sites and a restroom facility. Jenny Creek is on the north side of the reservoir and provides a creekside setting for picnicking and bank fishing.

Camp Creek is along a narrow reach on the north side of Iron Gate Reservoir. The surrounding hilly, semi-arid landscape and the reservoir provide pleasant views. Camp Creek has several campsites designed primarily for RV campers, with a large overflow RV camping area. Juniper Point Day Use Area and Campground has several picnic areas that are occasionally used as campsites, a fishing dock and restroom facilities.

Mirror Cove is a day use area and campground centrally located on the west side of the reservoir. The site offers several picnic sites that are occasionally used as campsites, a boat launch, and restroom facilities. This particular location is popular for group camping and is used extensively by local water-ski clubs. This boat launch is the nearest access to a competitive water-ski course placed in the western area of the reservoir.

Long Gulch Day Use Area and Campground is on the east side of the reservoir directly across from Overlook Point. Facilities at this location include picnic sites, restroom facilities, and a boat launch. Land along an adjacent ridge is occasionally used for dispersed camping and day use (PacifiCorp 2004).

Below Iron Gate Dam, the Iron Gate Fish Hatchery is operated by CDFG and includes a public day use area adjacent to the hatchery and an undeveloped boat launch across the river from the hatchery. The day use area includes a picnic area, a picnic shelter, visitor center/interpretive kiosk, restroom facilities, a trail to the river, and seasonal interpretive tours. Fishing is prohibited in this area, in addition to 3,500 feet downstream from the dam.

Visitor Use and Perception

PacifiCorp conducted a visitor survey in 2004 to assess recreational use and visitor perceptions of facilities associated with the Four Facilities, including the subject reservoirs. The majority of visitors surveyed (approximately 60 percent) were from Klamath County and Jackson County, Oregon. The remaining visitors were from California, approximately half of which came from Siskiyou County. When asked to indicate all activities participated in while visiting the subject reservoirs, more than half of the visitors surveys included resting/relaxing as one of the activities. When surveyed on their perception of crowding at the reservoirs, the mean score of respondents was 3.2 (on a 9-point scale from 1 – not crowded to 9 – extremely crowded), indicating that visitors did not feel overly crowded while participating in recreation activities. Further, approximately 39 percent of respondents had changed their visits to the subject reservoirs from other lakes in the area to avoid crowding. When surveyed regarding management options of the reservoirs, survey respondents indicated opposition to the collection of user fees at either day use sites or facility campgrounds (PacifiCorp 2004).

In response to the survey question “Has water quality ever affected your visit to the Klamath River area?” approximately two-thirds of recreational users of the subject reservoirs had negative perceptions of water quality, commenting on its color, turbidity, and odor. The source of visitor concerns was primarily the brown, foamy water in free-flowing reaches and regular, extensive algae blooms that occur throughout the reservoirs. Visitors reported that the algae produces bad odors, fouls fishing lines, and reduces the area available for fishing, swimming, and wading (FERC 2007).

Whitewater Boating Opportunities

Whitewater boating opportunities are provided on the J.C. Boyle Bypass Reach, the Hell’s Corner Reach, and the Copco 2 Bypass Reach. The J.C. Boyle Bypass Reach includes about 5 miles of the Klamath River downstream from J.C. Boyle Dam and upstream of the J.C. Boyle Powerhouse. This reach provides Class III to IV+ rapids, and acceptable whitewater boating flows range from 1,300 cfs to 1,800 cfs; however, this reach is typically dewatered with only 100 to 300 cfs base flow. Therefore, the majority of the year there is almost no boating use on this stretch of the river.

BLM manages whitewater boating use in the Hell's Corner Reach, a 16.4-mile reach from below J.C. Boyle Reservoir to the Fishing Access Site 1 take-out (see Figure 3.20-2b). This reach provides Class III to IV+ rapids during daily peaking flows from the PacifiCorp hydropower operations (between 10AM and 2PM), and acceptable whitewater boating flows range from 1,300 cfs to 3,500 cfs for commercial rafting and heavier loaded boats. Acceptable minimum flows for kayaking and private boaters are 1,000 cfs. Outside of the daily peaking flows, flow rates within this reach do not meet the acceptable range to create or enhance whitewater boating opportunities.

The average estimated annual whitewater boating use from 1994 through 2009 on this reach was 4,414 recreation days, peaking in the mid-1990s at around 6,000 recreation days per year. Whitewater boating use occurs typically during April through October, with about 80 percent of the commercial rafting use occurring during July through September. Commercial boating use accounted for about 93 percent of the whitewater boating use on this reach (United States Department of the Interior [DOI] 2011).

Commercial boating use is allowed by permit only. There is a set commercial capacity of 10 outfitters or 200 clients per day on this reach. There is no limit for private boating capacity, although BLM has established 250 persons per day as the overall whitewater boating carrying capacity of the reach. Factors that constrain the carrying capacity of the reach are vehicle congestion at the take-out locations near Copco 1 Reservoir and the limited size and number of areas that are available to scout rapids (FERC 2007). Rafting use in this area, above Copco 1 Reservoir in particular, depends upon operation of the J.C. Boyle Powerhouse upstream (FERC 2007).

The Copco 2 Bypass Reach is approximately 1.3 miles long, extending from Copco 2 Dam to the Copco 2 Powerhouse and whitewater boating opportunities are limited due to lack of flow. However, the reach could provide Class IV whitewater opportunities at acceptable flows range from 600 to 1,400 cfs.

3.20.3.3.2 Fishing Opportunities

PacifiCorp conducted a visitor use survey in 2002 to obtain information on existing visitor demand, needs, and recreational activities within the area between J.C. Boyle Reservoir and Iron Gate Dam. The results of the survey indicated that 33 percent of visitors to the area participate in bank fishing, both along the river and reservoirs. Survey respondents also indicated that fishing for trout on river reaches in this area is considered very good, and the two most popular reaches for fishing opportunities are Keno Reach downstream from Keno Dam and J.C. Boyle Bypass Reach downstream from J.C. Boyle Dam. Further downstream, opportunities for trout fishing exist below J.C. Boyle Powerhouse (Hell's Corner Reach). This reach (between J.C. Boyle Powerhouse and the State line) is popular with anglers, and catch records indicate good angler success, although fish size is typically smaller than fish caught below Keno Dam and rarely exceeds 16 inches (FERC 2007).

Recreational opportunities downstream from Hell's Corner Reach, between the California/ Oregon State border and Iron Gate Dam, are also quite popular, especially for

angling. In 1974, a 6-mile reach of the Klamath River, from the California/Oregon State line to Copco 1 Reservoir, was designated as Wild Trout water by the State of California and is managed under the Wild Trout Program (CDFG 2010) (see also Section 3.3, Aquatic Resources). Demand for recreational angling is high in this area. The Klamath River between the Copco 1 and Iron Gate Developments has poor public access and no documented fishing activity.

**3.20.3.4 Recreation Opportunities along the Klamath River Segment
 Downstream from Iron Gate Reservoir**

3.20.3.4.1 Recreation Facilities and Opportunities

The USFS (Klamath and Six Rivers National Forests) manages the majority of the river corridor from downstream from Iron Gate dam to the confluence with the Trinity River. Other areas downstream from Iron Gate area are also managed by the NPS, BLM, tribes and private land owners. Table 3.20-11 summarizes the river-based recreational opportunities available on the Klamath River downstream from Iron Gate Dam.

Table 3.20-11. River-Based Recreation Opportunities below Iron Gate Dam

Reach	Length (miles)	Current Recreation Opportunities
Iron Gate Dam to Shasta River	13	Sightseeing, Fishing (especially from boats), tubing and swimming, whitewater boating (rare), waterplay
Shasta River to Scott River	34	Sightseeing, Fishing, canoeing, whitewater boating, locational playboating, waterplay
Scott River to Indian Creek	36	Sightseeing, Fishing, canoeing, whitewater boating, waterplay
Indian Creek to Salmon River	40	Sightseeing, Fishing, whitewater boating, canoeing, hiking, waterplay
Salmon River to Trinity River	40	Sightseeing, Fishing, waterplay

Source: PacifiCorp 2004.

There are two privately developed recreation facilities along the river below Iron Gate Dam. One is R Ranch, near Hornbrook. The R Ranch is a large private recreation complex used by RV campers and day users who are members of the R Ranch Landowners' Association. The R Ranch has two separate campgrounds. Cottonwood Campground is just off of I-5, farther away from the Klamath River and offers full RV hookup sites and an RV dump station. Klamath Campground is a few miles east of Cottonwood and I-5 and 2 miles downstream from Iron Gate Dam along 1.7 miles of the Lower Klamath River. This campground contains a large lodge and provides opportunities to fish, hunt and view natural scenery and wildlife.

The Klamath Ranch Resort is a private recreation complex open to the public. It is located ¼ mile below Iron Gate dam and consists of a barn, private residence, historic restaurant, RV park and boat launches.

There are also private land areas near the I-5 corridor, in Seiad Valley, at Happy Camp, and near the mouth of the Salmon River at Somes Bar. In general, these areas have several homes and associated, sparsely populated, rural development. These areas have considerable opportunities to camp, swim, picnic, or relax along this portion of the river. There are also some opportunities for sightseeing, hiking, walking, or biking along the river. In addition, there are some popular short hikes from the river up the tributaries, such as Ukonom and Clear Creek. Land-based recreation points along the river are generally near developed access points for boaters and anglers and a few developed USFS and private campgrounds (PacifiCorp 2004). In addition, there are two National Scenic byways located along this segment of the river and within the Klamath and Six Rivers National Forests. The “State of Jefferson” National Forest Scenic Byway is located primarily on California State Highway 96 (State Highway 96) between Shasta River to Happy Camp, and the “Bigfoot” National Forest Scenic Byway is located on Highway 96 from Happy Camp to California State Highway 299 (State Highway 299). These byways provide excellent views for sightseers within the Klamath and Six Rivers National Forests and access to numerous other recreational activities (America’s National Scenic Byways 2010). Downstream from the Trinity River confluence, the Klamath River flows through the Yurok, Hoopa and Resighini Indian Reservations and Redwood National Park, as well as public land managed by the BLM and privately owned lands. A number of private RV and tent campgrounds are along the river in Redwood National Park, and just outside of the park in the City of Klamath. These campgrounds provide opportunities for bank fishing, camping, and picnicking. Other recreation opportunities in the area are associated with the national park and the adjacent State parks (Jedediah Smith, Del Norte Coast, and Prairie Creek Redwood State Parks), which offer hiking, hunting, and wildlife viewing. Table 3.20-4 provides a summary of the facilities associated with these parks.

Public Health Issues

As discussed in Section 3.2, Water Quality, concentrations of chlorophyll-a and *Microcystis aeruginosa* have exceeded World Health Organization (WHO) guidelines for protection from adverse effects in recent years, in both Copco 2 and Iron Gate reservoirs, as well as reaches of the Klamath River downstream from Iron Gate Dam. In 2005 and 2008, the North Coast Regional Water Quality Control Board (NCRWQCB), Karuk Tribe, United States Environmental Protection Agency (USEPA) and other local, State, and Federal agencies issued a warning to residents and recreational users of the river to use caution when near these algal blooms due to possible health effects of exposure to *Microcystis aeruginosa* and its microcystin toxin. Effects range from mild, non-life threatening skin conditions to permanent organ impairment and death, depending upon exposure time and intensity (FERC 2007). As identified in comments received during the scoping period for this Klamath Facilities Removal EIS/EIR, these water quality issues and public health warnings have resulted in reduced recreational activity in affected river segments in recent years.

3.20.3.4.2 Whitewater Boating Opportunities

Extensive whitewater boating opportunities exist downstream from Iron Gate Dam. Depending on the river segment and level of flow, there are opportunities for play, standard, and big water boating on Class II and III waters.¹ These runs are boatable in rafts, kayaks, inflatable kayaks, and open canoes. Table 3.20-6 summarizes the acceptable flow ranges for reaches downstream from Iron Gate Dam.

Although not as challenging as the Hell’s Corner Reach upstream, there are a few rapids that are sometimes rated Class IV, including Hamburg and Upper Savage on the Otter’s Playpen run, Rattlesnake on the day-use run below Happy Camp, and Dragon’s Tooth between Ferry Point and Coon Creek Access. There is also a well-known kayak playboating wave known as the “School House Wave” between Skehan Bar and Gottville. This wave is typically available during low to moderate summer flows and is popular with local kayakers from the Mount Shasta, Klamath Falls, and Ashland areas (PacifiCorp 2004). There is also a Class VI rapid at Ishi Pishi Falls (Somes Bar) that boaters are strongly advised to portage around (Cascade Outfitters 2010).

The primary whitewater boating season is in summer (June through August), when water temperatures are warm; however, the river can be boated in most months of the year (PacifiCorp 2004). There is less whitewater rafting downstream from the Trinity River confluence after the river turns northwest into strong prevailing winds. There are fewer developed river access points along this reach than in the reaches upstream. This reach is located within the boundaries of the Yurok Tribe Indian Reservation. Data collected by the USFS and BLM indicate that substantially more whitewater boating occurs on the Klamath River below Iron Gate Dam than in the Klamath River upstream to J.C. Boyle Dam. From 1994 through 2009, the average annual number of user days was 14,392 per year. However, whitewater boating in this portion of the Klamath River has decreased somewhat in recent years. In part, this decline is due to the presence of microcystin blooms in the river. Total user days from 2000 through 2003 ranged from 13,976 to 15,349 per year, whereas from 2005 through 2009, total user days ranged from 11,751 to 15,279 per year (DOI 2011).

3.20.3.4.3 Fishing Opportunities

The Klamath River downstream from Iron Gate Dam has high quality angling opportunities extending nearly 200 miles to the Pacific Ocean and is open to fishing year-round. This reach, designated a national WSR (see Section 3.20.3.5 below) attracts and supports several fishing outfitter services that focus on salmon, steelhead, and trout fisheries. A review of outfitters conducted as part of the Secretarial Determination process identified over 50 outfitters providing sport fishing, boat fishing, and/or fly fishing trips on the Klamath River. Twenty-seven river access sites within the Klamath National Forest provide access for fishing in this section of the river. Use at the sites varies; however, most are rated as light usage (Klamath National Forest 2010). Tables 3.20-12 and 3.20-13 provide recent use data for Chinook salmon and steelhead fishing on the Klamath River. As shown in the table, angler success varied annually, but

¹ As rated by the American Whitewater International Scale of Difficulty (AW 1998).

was much greater in the first half of the decade than in the latter half. The USFS reported that the decline in fish production in the past few decades triggered a similar decline in the guide and resort industry, as well as sport fisheries (FERC 2007) (see also Section 3.15, Socioeconomics).

In addition, decreased abundance of anadromous fish species resulted in restrictions on the fishing seasons for certain runs of Chinook salmon in 2006 and 2008 (National Oceanic and Atmospheric Administration [NOAA] Fisheries Service 2006).

Downstream from the Trinity River confluence, angling in the Klamath River is dependent on the annual status of the fall-run Chinook salmon run, so the number of businesses that offer angling guide services changes from year to year. The main run of

Klamath River Chinook salmon peaks in late fall and is normally over by mid-January each year; the steelhead season normally starts in November (see also Section 3.3, Aquatic Resources).

Anglers fish from boats and the bank. Most of the boat fishing occurs from drift boats or rafts. Fishing regulations allow anglers to keep up to five trout per day and most of the fishing activity occurs in summer and fall. Limits on salmon and steelhead have varied over the years, and regulations depend on whether the fish is wild or from the Iron Gate Hatchery. Most anglers catch and release steelhead (PacifiCorp 2004).

3.20.3.5 Wild and Scenic Rivers Conditions

Two segments of the mainstem Klamath River are designated WSRs, one in Oregon and one in California (Figure 3.20-3). The reach in Oregon, between the J.C. Boyle Powerhouse and the Oregon/California State line was designated a WSR in 1994. In California, the entire river beginning 3,600 feet below Iron Gate Dam to the estuary was designated a WSR in 1981 because of the outstandingly remarkable anadromous fisheries, including that of salmon and steelhead trout. WSR boundaries include variable-width linear corridors which typically include not more than 320 acres per linear mile (averaging up to approximately 0.5 miles in width along the river corridor); however, some protections for designated outstanding remarkable values can extend beyond the designated boundaries.

3.20.3.5.1 Oregon Klamath River WSR Component

The Oregon Klamath WSR, beginning immediately downstream from the J.C. Boyle Powerhouse and flowing 11 miles to its terminus at the Oregon/California State line, was added to the NWSRS through Section 2(a)(ii) of the WSR Act. The river is classified as scenic and possesses outstandingly remarkable scenic, recreational, fish, wildlife, pre-history, history, and American Indian Traditional Use values. The following subsections summarize the existing conditions in the Klamath River at the time of the WSR designation (1994) of the Oregon component.

Scenic

The Upper Klamath River (upstream of Iron Gate Dam) was evaluated by BLM in 1977 and 1981, and received a Scenic Quality Class A rating, the highest scenic quality classification. The 2006 Preliminary Determination Report (completed for the Section 7 WSR requirement during FERC relicensing of the PacifiCorp facilities) stated that scenery associated with the 11 mile Upper Klamath WSR is the main visual element in the region and exhibits more landform variety than the surrounding plateau (Bonacker et al. 2007). As the river canyon cuts across the plateau, it is characterized by cliffs, steep slopes, upland benches, alluvial terraces and the meandering river channel, “which can all be encompassed in a single view” (Bonacker et al. 2007). The unique landforms, water, and vegetation create an ever-changing landscape from desert to more mountainous terrain, and steep canyons and vertical cliffs with diverse vegetation (Bonacker et al. 2007).

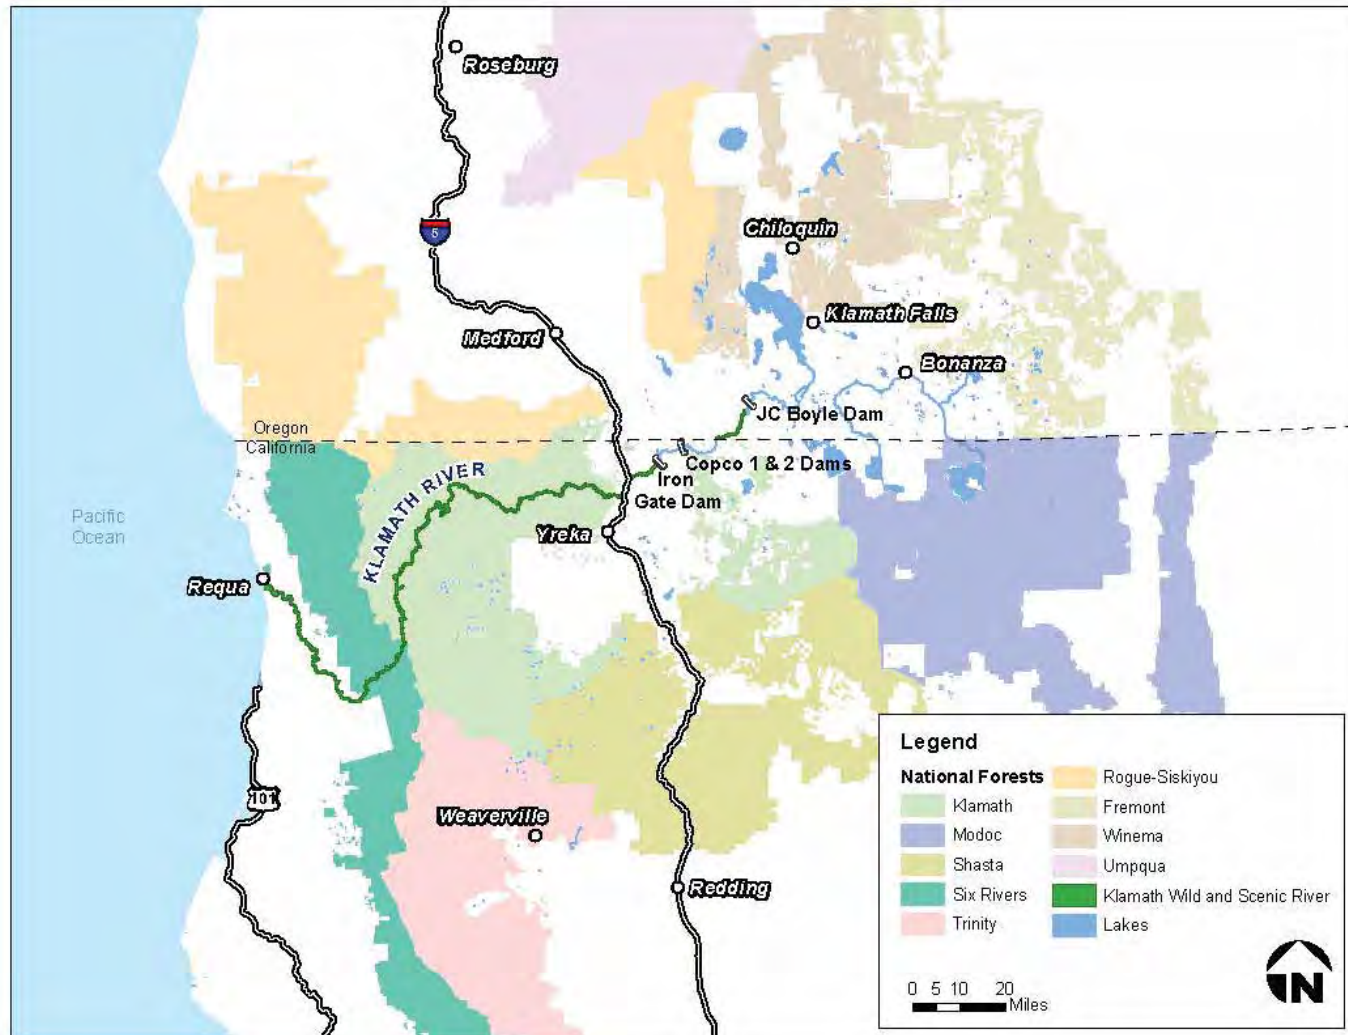

Figure 3.20-3. Klamath Wild and Scenic River Corridor.

Recreation

In the WSR designation, whitewater boating and recreational fishing were specifically mentioned by the Secretary as outstandingly remarkable values of the Upper Klamath WSR. Other popular recreation activities that occurred and continue within the recreation settings along the WSR reach include sightseeing, camping, hunting, OHV use, river swimming and water play, and upstream reservoir fishing and power boating (Bonacker et al. 2007). However, poor water quality conditions have adversely affected water play and river swimming within the WSR area (see section below). In 1994, at the time of the designation, the typical flow regime consisted of reliable and predictable daily hydropower peaking as provided by the KHP. Releases typically peaked in the mid-morning hours, and base flows typically occurred during the hours from late afternoon/early evening until morning. These releases provide whitewater boating opportunities throughout the summer and fall.

Water Quality

As stated in the 2006 Preliminary WSR Determination Report for the FERC relicensing EIS, during the fall, winter, and spring, at base flow, the water appearance is not influenced by the addition of spring water because water released from the reservoir has less algae, nutrients, and turbidity. However, at the time of designation, summer base flow resulted in shallow, slow-moving waters with large amounts of visibly algae-covered rocks.

Peaking operations from the KHP change the relative proportions of cool spring water from the Bypass Reach and warm water from the reservoir and powerhouse, which causes large artificial diurnal temperature fluctuations with higher daily maximum temperatures during power generation as compared to a run-of-river scenario. During peaking events, water appearance changes to a brownish, murky color; it is difficult to see to any depth; and large quantities of algal foam are produced and coalesce in river eddies below major rapids. During off-peak periods the relative contribution of cold clear spring discharge from the bypass reach dominates the flow (Bonacker et al. 2007).

Fisheries

The Upper Klamath River supports a genetically unique population of redband trout and two endangered species, the Lost River and shortnose suckers. The WSR designation report specified redband trout as an outstandingly remarkable value and also listed federally endangered Lost River and shortnose suckers, Klamath largescale suckers, and slender sculpin as “notable species.” At the time of designation, native fish species known or suspected to occur in the Upper Klamath WSR included redband/rainbow trout; Klamath smallscale, Klamath largescale, shortnose, and Lost River suckers; tui and blue chubs; lampreys (perhaps Klamath and Klamath pit brook); sculpins (perhaps marbled only); and Klamath speckled dace (Bonacker, et al. 2007).

Wildlife

The eligibility report identified that the WSR component provided a diversity of habitats for national, regional, and locally important populations of indigenous wildlife species, including exceptional populations of birds of prey, game and other birds, ringtail cats,

river otters, and other species. Numerous Federal and/or State-designated threatened or endangered species (including Federal and State species of concern) including peregrine falcons (*Falco peregrinus*), western pond turtles (*Clemmys marmorata marmorata*), and Townsend's big-eared bats (*Corynorhinus townsendii*) are dependent on the Klamath River. In addition, a high percentage of the wildlife species found in the Oregon Klamath WSR were identified to be directly dependent upon, or disproportionately use, riparian habitat for breeding, foraging, resting, and migration (Bonacker et al. 2007).

3.20.3.5.2 California Klamath River WSR Component

The segment of the Klamath River in California, beginning 3,600 feet below Iron Gate Dam and flowing 189 miles to the Pacific Ocean, as well as portions of three tributaries (Salmon and Scott Rivers and Wooley Creek) were added to the NWSRS in 1981 through Section 2(a)(ii) of the WSR Act. The mainstem California Klamath WSR is classified as recreational with portions of the tributaries classified as scenic and wild. The anadromous fishery is the outstandingly remarkable value for the entire 286 miles of the designated component, which includes the tributaries. The following subsections summarize the existing conditions in the Klamath River at the time of the WSR designation.

Scenic

Scenery within the California Klamath WSR is dominated by natural settings. Its characteristic river flows, water appearance, anadromous fish and riparian vegetation within a forested river canyon are the primary scenic aspects. Since 1981, flow regimes have varied moderately in response to water resource competition within the Klamath Basin. During summer months, these have typically been caused by water diversions (Van de Water et al. 2006). Also, as described in Sections 3.2, Water Quality, and 3.19, Scenic Quality, reduced water clarity and discoloration resulting from algae blooms has impaired the historic scenic character of reaches downstream from Iron Gate Dam. The level of reduced water clarity and discoloration and resulting scenic quality effects is dependent on viewer location. Views from on-river, in-river, or riverside viewpoints are most likely to display substantial changes to scenic quality indicators, while these changes are less likely to be noticed as viewed from nearby river canyon roadways and communities.

The river's lowest historic flows since the WSR designation can be identified by gage data from United States Geological Survey (USGS) gage no.11516530 near Iron Gate Dam. The lowest monthly summer time flows within the 21-year historical record at Iron Gate Dam before 1981 represents the lower limits of characteristic flow variability, which still expresses its historic scenic character. Before 1981, USGS records show no Iron Gate Dam flow releases of less than 700 cfs; however, flows of less than 700 cfs occurred during 17 months between 1981 and 2004 (Van de Water et al. 2006). Since 2004, no flows of less than 700 cfs have occurred. The lowest monthly mean flows occur in summer (July and August) and have ranged from 823 to 1,373 cfs (USGS 2011). Similar to the scenic quality changes related to water quality conditions described above,

seasonal and project-induced changes in flow and resulting scenic quality changes are more likely to be observed by on-water, in-water and riverside viewpoints than nearby river canyon roadways and community viewpoints.

Recreation

The flows released from Iron Gate Dam greatly influence the river’s summer recreation season’s whitewater boatability, challenge levels, safety hazards, potential for equipment damage, and the opportunity to access and experience the river’s full range of rapids and channels. Exceptionally low summer time flow releases are especially adverse to California Klamath WSR boating activities. Table 3.20-14 compares flows at the time of the 1981 designation to flow conditions required for whitewater boating and recreational fishing (see Table 3.20-6 for optimal flow ranges) (Van de Water et al. 2006).

Table 3.20-14. Comparison of 1981 Flows to the Acceptable Range for Whitewater Boating and Fishing

Month	Flows (cfs)	Whitewater Boating	Fishing
January	1,300	In acceptable boating flow range/optimal playboating range	In optimal range
February	1,300	In acceptable boating flow range/optimal playboating range	In optimal range
March	1,300	In acceptable boating flow range/optimal playboating range	In optimal range
April	1,300	In acceptable boating flow range/optimal playboating range	In optimal range
May	1,000	In acceptable boating flow range/optimal playboating range	In optimal range
June	710	Does not meet minimum boatable flow or playboating opportunities	Does not meet minimum fishing flow
July	710	Does not meet minimum boatable flow or playboating opportunities	Does not meet minimum fishing flow
August	1,000	In acceptable boating flow range/optimal playboating range	In optimal range
September	1,300	In acceptable boating flow range/optimal playboating range	In optimal range
October	1,300	In acceptable boating flow range/optimal playboating range	In optimal range
November	1,300	In acceptable boating flow range/optimal playboating range	In optimal range
December	1,300	In acceptable boating flow range/optimal playboating range	In optimal range

Key:

cfs: cubic feet per second

Although precise estimates of available recreation days in 1981 are not available, commercial recreational whitewater boating activity on the Klamath National Forest portion of the California Klamath WSR increased by approximately 34 percent between

1981 and 2005 (Van de Water et al. 2006). However, commercial activity on the lower Klamath River has decreased somewhat since 2005 from a recorded 10,695 user days to 8,230 user days in 2009, a trend consistent with other western rivers. Private recreational whitewater boating activity has followed a similar pattern, with the greatest number of user days between 1995 and 2005 (ranging from 4,193 to 5,230) and decreasing somewhat since 2005 to a low of 3,525 user days in 2009, as summarized in Section 3.15, Socioeconomics (DOI 2011).

Water Quality

Water quality issues have existed since the time of WSR designation and there is evidence indicating that these issues may have increased since that time, and even more progressively over the past 5 years (Kann and Corum 2009). Water quality issues in the Klamath, including algae blooms and microcystin toxin from one species of blue-green algae, affect river recreation users (see discussion of Public Health Issues in Section 3.20.3.4 above). Results of the toxic algal monitoring program conducted by the Karuk Tribe between 2005 and 2007 at 16 near shore stations in the Klamath River below Iron Gate Dam indicate that nearly 60 percent of samples taken between June and September exceeded the moderate risk level as defined by the WHO (Kann and Corum 2009). Additional sampling conducted in 2007 shows that the microcystin toxin is found as far downstream as the Yurok Reservation, near the river mouth (Kann 2006). In addition, the entire length of the California WSR currently does not meet NCRWQCB water quality objectives for temperature (NCRWQCB 2007). A detailed description of existing water quality is provided in Section 3.2, Water Quality.

Fisheries

The Klamath River was designated a WSR because of its free-flowing condition and its outstandingly remarkable anadromous fisheries, including that of salmon and steelhead trout. Even at the time of designation, decreasing salmonid trends in the Klamath River system were identified as being affected by various factors, including dam construction and operations related to hydropower generation in the Klamath River. Such factors have resulted in increased summer water temperatures, changed the natural flow regime, decreased dissolved oxygen levels in portions of the river, and blocked access to more than 350 miles of spawning, incubation, and rearing habitat. Scientific evidence shows that Chinook salmon, coho salmon, cutthroat trout, and steelhead trout were historically present above Iron Gate Dam (Hamilton et al. 2005).

According to a 1981 California Department of Water Resources (CDWR) study, spawning conditions in the reach immediately downstream from Iron Gate Dam were already impaired due to a coarsening of the bed below the dam. Although the reach below Iron Gate Dam was historically a prime spawning area, by 1981 the reach produced few salmon and the riffles within the reach contained cobbles too large for salmon to move. Prior to the 1981 WSR designation, the reach between Iron Gate Dam and Shasta River was scoured by daily peak flows from Copco 1 and Copco 2 operations prior to the construction of Iron Gate Dam (Van de Water et al. 2006).

Streambed armoring as a result of low flows and reduced gravel recruitment can decrease habitat diversity within channels, making the river less hospitable to juvenile salmonids. Armoring can also lead to the cementation of spawning gravels, impairing the ability of spawning adults to make redds. Armoring can also decrease the amount of habitat available (interstitial spaces) to macroinvertebrates, an important food source for fish. Given the findings of the 2006 study, it appears that much of the riverbed coarsening had occurred prior to the WSR designation (Van de Water et al. 2006). However, impacts from dams progress over time so one would expect that continued sediment depletion (by the retention of sediment behind the dams) would continue to worsen spawning habitat below the dam (Ligon et al. 1995; Kondolf 1997; and Grant et al. 2003).

River flows also affect fisheries' population and abundance. Table 3.20-14 shows the monthly flows at the time of the WSR designation. Flows are a key component of cumulative effects from water management on the aquatic environment. The flow regime downstream from Iron Gate Dam affects aquatic resources through instream flow influences on physical habitat (depth, velocity, substrate, and cover) and on water quality that may affect the prevalence of disease pathogens (Bartholow et al. 2005).

Estimates of abundance for anadromous fisheries at the time of the WSR designation are not available for all species. Table 3.20-15 provides estimates of abundance at the time of designation, or as near as possible to the time of designation for those species for which data is available. As discussed in Section 3.3, Aquatic Resources, the abundance of anadromous fisheries has decreased since the time of the WSR designation. Specific units of coho salmon in the Klamath River were listed as threatened under the ESA in 1997. Similarly, the green sturgeon was listed by NOAA Fisheries Service as a Species of Concern in 2005 and designated as threatened under the ESA in 2010. The Lost River and shortnose sucker were designated as endangered in 1988 after the WSR designation in California and after the designation in Oregon.

Table 3.20-15. Estimated Abundance of Fish Species at the 1981 WSR Designation

Species	Estimated Abundance
fall Chinook salmon	Natural spawners – 4,000 (1981)
	Iron Gate hatchery spawners – 21,595 (1981)
coho salmon	3,400 (1984)
summer Steelhead	110,000 (average 1977-1991)
winter Steelhead	20,000 (average 1977-1991)

Source: Van de Water et al. 2006

Wildlife

Wildlife populations have not been systematically surveyed on the Klamath River. Baseline data were not collected in 1981; therefore, population numbers or trends are not available for most species in specific areas like the WSR corridor.

Riparian vegetation provides habitat for feeding, breeding, and sheltering for willow flycatchers, western pond turtles (a species of special concern in California) and various other wildlife species along the river. There is no reference condition for the riparian vegetation in 1981 (Van de Water et al. 2006). The project area includes a large number and diversity of wildlife species. Surveys conducted by PacifiCorp in 2002 and 2003 identified five amphibian species, numerous bird species, including 19 species of birds of prey, and numerous mammal species, including black-tailed jackrabbit, mule deer, and California ground squirrels. See Section 3.5, Terrestrial Resources, for further discussion of wildlife populations within the Klamath River corridor.

3.20.3.5.3 Eligible and Suitable WSR Section on the Klamath River

In 1990, BLM found the 5.3-mile section of the Klamath River from the Oregon/California State line to the slack water of Copco 1 Reservoir to be eligible and suitable for WSR designation under Section 5(d)(1) of the Act. The river segment is free-flowing and possesses outstandingly remarkable scenic, recreational, fish, and wildlife values. This river segment is not a designated WSR and is not protected under the WSRA and its Section 7(a) requirements. The BLM is required within its authorities, to protect this suitable river segment's free-flowing character, water quality, and outstandingly remarkable river values. This segment of the Klamath River is also listed on the Nationwide Rivers Inventory (NRI) (NPS 2009). If a river is listed in the NRI, the Federal agency involved with the action must consult with the land managing agency in an attempt to avoid or mitigate adverse effects of any proposed water resources projects. This consultation is required pursuant to a directive from the Council on Environmental Quality.

3.20.4 Environmental Consequences

3.20.4.1 Effects Determination Methods

This discussion of environmental effects considers the implications of the Proposed Action and identified alternatives on the potential changes to river- and reservoir-based recreation opportunities, activities, and settings within the study area. The relocation of the City of Yreka's water supply pipeline is not expected to result in any impacts to recreational resources; therefore, it is not addressed in this section of the EIS/EIR. The analysis presented below includes an assessment of both short-term and long-term effects on access, flow-dependent recreational activities, recreational fishing, and other recreational activities associated with the existing Klamath River corridor and reservoir recreational facilities within the study area.

3.20.4.1.1 Recreational Setting, Facilities, and Access

Likely changes to recreational use and access under each identified alternative were assessed qualitatively, including changes from reservoir-based recreational opportunities to more river-based opportunities in the areas where the dams, recreational facilities, and/or PacifiCorp facilities would be removed. The short-term effects analysis includes a discussion of potential areas where recreational access would be restricted due to

construction activities. The assessment of long-term effects discusses potential changes in the recreational setting and experience, changes in water quality and reservoir area revegetation.

3.20.4.1.2 Whitewater Boating Opportunities

Optimal and acceptable flows for whitewater boating opportunities along reaches of the Klamath River were assessed as a part of the technical review completed for the Secretarial Determination. The range of acceptable flows resulted from the Final Technical Report, Klamath Hydroelectric Project (PacifiCorp 2004b). Flow values that fall within these ranges are considered acceptable flow levels for the various activities (see Table 3.20-6).

The Lead Agencies conducted hydrologic modeling to assess changes in the availability of acceptable flows under the various alternatives. The Lead Agencies subjected the modeling results for each water year type to a statistical analysis (paired T-tests) to determine whether the difference in number of days meeting the acceptable range of flows following dam removal (both on an annual and monthly basis) would be statistically significant. The Lead Agencies used a qualitative approach to assess the effects of the identified alternatives on whitewater boating access and existing whitewater boating opportunities.

3.20.4.1.3 Recreational Fishing Opportunities

The Lead Agencies used the results of the hydrologic modeling to; determine whether changes in flow would affect recreational fishing opportunities (i.e., number of days with optimal flows for recreational fishing), qualitatively assess potential changes in fisheries populations and abundance; and determine effects of changes from reservoir-based fishing opportunities to river-based opportunities.

3.20.4.1.4 Other Recreational Opportunities

The analysis also includes an assessment of other recreational activities, such as sightseeing, swimming/wading/tubing, fish and wildlife viewing, and camping that occur within the river corridor and a qualitative discussion of the effects of the various alternatives on these activities. The discussion here covers both anticipated short-term effects, such as construction-related effects, and long-term effects, such as changes in reservoir-based swimming opportunities.

3.20.4.2 Recreation Significance Criteria

For the purposes of the EIS/EIR, the following Recreation impacts would be significant if they would result in the following:

- Substantial restrictions on recreational access or reduction in the quality of recreational experiences in the vicinity of the subject reservoirs;
- Substantial decreases in the availability of reservoir/lake-based recreational opportunities;
- Substantial reduction in the quality of water-contact-based recreational activities;
- Substantial decreases in access for whitewater boating opportunities;

- Substantial changes in the amount of days providing acceptable flows for recreational activities.

3.20.4.3 Effects Determinations

3.20.4.3.1 Alternative 1: No Action/No Project

The No Action/No Project Alternative would not change existing recreation access and opportunities. Under the No Action/No Project Alternative, no change to existing conditions, recreational facilities or opportunities at J.C. Boyle, Copco 1, or Iron Gate Reservoirs would occur. Similarly, whitewater boating and recreational fishing opportunities in reaches between J.C. Boyle Dam and Copco Reservoir and downstream from Iron Gate Dam would remain as described in the Affected Environment. As described in the Affected Environment, recreation activities in the reaches between J.C. Boyle Dam and Copco Reservoir (e.g., Hell's Corner Reach) are flow-dependent and rely on daily peaking hydropower operations.

Under the No Action/No Project Alternative, these operations would continue and opportunities for whitewater boating and fishing in these reaches would remain as described. Within the subject reservoirs and downstream from Iron Gate Dam, poor water quality conditions and decreased abundance of anadromous fish species have resulted in adverse existing conditions for recreational activities, including complete closures of fishing seasons for certain species and public health warnings against water-contact-based activities during algal blooms in the summer. **Under the No Action/No Project Alternative, existing impacts on recreational fishing within the river and water-contact-based activities at the subject reservoirs would have no change from existing conditions.**

3.20.4.3.2 Ongoing Restoration Actions

Ongoing restoration actions would continue to take place under the No Action/No Project Alternative. Construction and implementation activities associated with these ongoing projects could result in effects to recreational resources and opportunities in the areas where construction takes place.

Ongoing actions considered for impact to recreational resources under the No Action/No Project Alternative include:

- Ongoing restoration actions
- Agency Lake and Barnes Ranches project

Construction activities associated with ongoing programs could temporarily restrict access to recreational opportunities. Construction activities including channel construction, floodplain rehabilitation, fish passage and facilities construction, and breaching levees would likely involve the use of heavy equipment along floodplain and riparian areas and could result in restrictions to public access for recreational activities, such as sightseeing, bank fishing, swimming, and wading. Because restoration activities would occur throughout the entire basin, specific sections of the river could be closed for a period of time throughout implementation of the ongoing restoration programs.

However, as described in the Affected Environment section, there are a number of recreational areas offering similar activities and settings throughout the basin. It is likely that for any particular project, there would be an alternative recreational area nearby that could be used during temporary closures. **Thus, potential impacts to recreational opportunities would be less than significant. Implementation of specific projects will require future environmental compliance as appropriate.**

Construction activities could result in short-term water quality impacts which could affect recreational opportunities. Erosion and sedimentation during construction activities has the potential to temporarily decrease water quality and reduce water visibility for boaters, swimmers, and fisherman. These short-term water quality impacts would be anticipated to occur throughout the basin where construction activities take place. Specific sections of the river could be affected for a period of time throughout implementation of the ongoing restoration programs. However, following implementation and related construction activities for ongoing restoration programs water quality and clarity in Upper Klamath Lake would be expected to improve. Additionally, as described above, short-term impacts would be offset by the ability of visitors and local recreationalists to use recreational areas with similar activities and settings throughout the basin. **Potential impacts would be short term and, with implementation of construction best management practices (BMPs), would cause less than significant water quality related recreational impacts. Implementation of specific projects will require future environmental compliance as appropriate.**

Ongoing actions correcting fish passage issues, reintroducing and monitoring fish species, and restoring aquatic habitat could increase recreational fishing and wildlife viewing opportunities in the basin. It is expected that correction of fish passage issues throughout the basin would restore fish access to new and historic habitats and result in increased fish populations. Ongoing restoration programs could continue to improve fish passage and habitat conditions in the basin which could benefit recreational fishing opportunities. **It is expected that continued implementation of restoration programs would benefit recreational experiences throughout the Klamath Basin. Implementation of specific projects will require future environmental compliance as appropriate.**

3.20.4.3.3 Alternative 2: Full Facilities Removal of Four Dams (Proposed Action)

Demolition activities could temporarily restrict recreational access in the vicinity of the reservoirs. Short-term demolition activities associated with dam removal would result in temporary loss of access to recreational facilities at the subject reservoirs and associated reservoir-based recreational opportunities. Access could remain restricted for an additional period following completion of dam removal as restoration activities are conducted on the former reservoir area and existing recreational areas are modified to accommodate the new river channel. However, as described in Section 3.20.3.1, Regional Opportunities, a number of reservoirs and lakes are present within and adjacent to the Klamath Basin and provide similar opportunities for recreational activity. **Therefore, temporary impacts on recreational access in the vicinity of the subject reservoirs would be less than significant.**

Temporary impacts from demolition activity (i.e., increased noise and dust) could decrease the quality of recreational experiences in the vicinity of the reservoirs. As described in Section 3.9, Air Quality, and Section 3.23, Noise and Vibration, the use of heavy vehicles and equipment during dam removal would result in a temporary increase in dust and ambient noise in the vicinity of the subject reservoirs. These increases could indirectly result in a decrease in the quality of recreational experiences at nearby facilities that would not have restricted access during construction (e.g., trails and private parks not directly affected by construction). Specific effects related to noise and dust are discussed in detail in their respective sections; with regard to recreational activities, increases in ambient noise and air pollutants could impede visitors' ability to rest and relax, and disrupt bird and wildlife viewing opportunities. These effects would last for the duration of demolition activity; however, as shown in Figures 3.20-2(a-c), the majority of recreation facilities and access points at the subject reservoirs are located a distance away from the dams and would continue to provide opportunities for recreation until drawdown is completed. Further, as described in Section 3.20.3.1, Regional Opportunities, numerous other recreational areas are available within the vicinity of the subject reservoirs that provide similar recreational opportunities. **Therefore, these temporary noise and dust impacts would be less than significant.**

Dam removal could permanently decrease the availability of reservoir/lake-based recreational opportunities in the area of analysis. The removal of the Four Facilities would eliminate existing opportunities for reservoir-based recreation activities, such as power boating, waterskiing, lake swimming, and flat water boat angling, provided at J.C. Boyle, Copco 1, and Iron Gate Reservoirs. As discussed in the Affected Environment section, the subject reservoirs are popular recreational areas for sightseeing, fishing, camping, swimming, boating, and wildlife viewing and attract visitors primarily from the surrounding communities in Klamath and Jackson County, Oregon and Siskiyou County, California. As indicated in the responses to visitor use surveys conducted by PacifiCorp, the reservoirs are popular recreation areas in part because they are uncrowded relative to other lakes in the area and do not require user fees. Some activities associated with reservoir recreation could still be possible in the newly created river channel (e.g., swimming and wading). However, due to increased flows, certain reservoir-based recreation such as swimming opportunities and flat water boating may be limited in the newly formed river channel during certain times of year and in wet water years. Additionally, the types of river-based recreational opportunities available following dam removal including camping in a river setting as opposed to camping in a lake/reservoir setting, may not appeal to the same recreational users who currently visit and recreate at J.C. Boyle, Copco 1, and Iron Gate Reservoirs. Thus, there would be a permanent loss of reservoir-based recreational opportunities at the project reservoirs. While new recreation opportunities would exist along the newly formed river, there could be a change in user type. People specifically seeking lake or reservoir-based recreation would have to travel to and use other lakes and reservoirs in the region.

As shown in Table 3.20-4, a number of other lakes and reservoirs are in the vicinity of the subject reservoirs and provide similar opportunities for recreation in an uncrowded

setting. Specifically, Table 3.20-4 shows that Fourmile Lake, Agency Lake, Applegate Reservoir, and Medicine Lake, located from 26-46 miles away from the subject reservoirs, each have low generalized use levels as well as similar or greater surface area, number of developed campsites, and number of improved boat launches. These four regional lakes have fewer developed picnic areas (PacifiCorp 2004). Given the presence and proximity of these regional lakes as well as the other lakes and reservoirs summarized in Table 3.20-4, the loss of the subject reservoirs would not result in a substantial decrease in regional lake-based recreational opportunities. Further, recreational opportunities would remain available on and along the newly created river channel. **Therefore, impacts on the regional availability of reservoir-based recreational opportunities would be less than significant.**

Dam removal could permanently remove recreational facilities associated with the reservoirs. Under the Proposed Action, the recreational facilities constructed to accommodate reservoir recreation, with the exception of Topsy Campground, Fall Creek and Jenny Creek Day Use Areas, and the Iron Gate Fish Hatchery Day Use Area, would be completely removed and the former recreation areas, parking areas, and access trails would be regraded and revegetated (Reclamation 2011). This would result in a permanent decrease in river access points. Dam removal would permanently decrease the availability of reservoir recreational opportunities (as described above), and the removal of existing recreational facilities would limit access to recreational opportunities along and within the newly formed river channel. However, as described in Section 3.20.3.1 Regional Opportunities, a number of reservoirs and lakes are present within and adjacent to the Klamath Basin and provide similar opportunities for recreational activity. **These impacts on recreational facilities associated with the subject reservoirs would be considered permanent; however, implementation of Mitigation Measure REC-1, while providing for a different type of use would ensure that these impacts in the long term would be less than significant.**

Dam removal could adversely affect developed recreational facilities upstream and downstream from the subject reservoirs. No impacts on recreational facilities upstream of the dam removal sites would occur as a result of removal of the Four Facilities because any changes to flow and water quality would occur downstream from J.C. Boyle Dam and Topsy Recreation site on J.C. Boyle Reservoir will be reconfigured to provide river access. However, as discussed in Section 3.3, Aquatic Resources, removal of the dams would help restore the presence of anadromous fish to the Klamath River above J.C. Boyle reservoir which would beneficially affect recreational fishing at these upstream facilities. Removal of the dams is expected to result in water quality improvements downstream from Iron Gate Dam (see Section 3.2, Water Quality), which could improve visitor perceptions and attract a greater number of visitors to existing recreational facilities. However, land-based facilities would not be physically affected by removal of the dams and drawdown of the reservoirs, since, as discussed in Section 3.11, Geology, Soils, and Geologic Hazards. The river is largely confined by bedrock and there would be little change to floodplain areas or the river channel itself. **Any impacts on upstream and downstream recreational facilities would be less than significant.**

Sediment release downstream during reservoir drawdown could decrease the quality of water-contact-based recreational opportunities. As discussed in Section 3.2, Water Quality, drawdown of the reservoirs would result in short-term increases in turbidity downstream from the PacifiCorp reservoirs. Turbidity would be most pronounced immediately downstream from Iron Gate Dam (between Iron Gate Dam and Bogus Creek), and less so farther downstream, and is expected to be flushed through the system quickly (less than 2 years). This increase in turbidity would reduce visibility for boaters, swimmers, and fisherman during the sediment flushing period and could result in reduced public draw for these activities (e.g., swimmers might be less likely to enter the river and fisherman might be less successful due to the reduced water clarity). Increased turbidity would also affect safety considerations during swimming if swimmers are unable to see the river bottom or navigate around obstacles, such as large boulders or logs beneath the water surface. However, impacts would be temporary; following completion of reservoir drawdown activities, water quality and clarity would be expected to improve as sediments are flushed downstream and into the Pacific Ocean. Impacts would not be widespread throughout the river; opportunities for fishing and swimming in non-turbid waters would remain available during the drawdown period.

Sediment release could also decrease the quality of water-contact-based recreational opportunities if sediment released downstream resulted in longer-term deposition in pools, eddies, slack water, and beaches and decreased the availability of these areas for recreational activity. As discussed in Section 3.11, Geology, Soils, and Geologic Hazards, modeling was conducted to determine the potential for such deposition following dam removal. The results of the modeling indicated that following dam removal, deposition would occur primarily between Iron Gate Dam and Cottonwood Creek and there would be no substantial change in river bed elevation. The Proposed Action was developed to allow reservoir drawdown to occur during winter months when precipitation, river flows, and turbidity are naturally highest. Suspended sediments would be highest during the period of greatest reservoir drawdown (January through Mid March 2020), as erodible material behind the dams is mobilized downstream (Reclamation 2012). During normal to dry water years, suspended sediment concentrations would begin to decline in late March 2020 and would continue declining through early summer 2020 (Reclamation 2012). If it is a wet year, it may take longer to drain the reservoirs and the high concentrations may extend until June. Suspended sediments will be near background conditions for all water year types within the first year following removal. (Aquatic Resources Section 3.4.3.2.1.1) Therefore, it is unlikely that sediment release would decrease the availability of pools, eddies, or beaches for recreational activity, even temporarily. **Therefore, impacts on the quality of water-contact-based recreational opportunities would be short term and less than significant.**

Changes in water quality associated with dam removal could positively affect water-contact-based recreational opportunities. Dam removal is expected to result in long-term improvements in water quality, notably decreased prevalence of microcystin toxin (see Section 3.2, Water Quality). As discussed in Section 3.2, Water Quality and

3.20.3.2 above, microcystin toxin has been associated with public health risks for recreational bathing waters and health warnings issued in 2005 and 2008 by the USEPA and other agencies warned recreation visitors to use caution due to potential health effects. In addition, about two-thirds of recreation visitors to the subject reservoirs had negative perceptions of water quality, stating concerns of bad odors and algae blooms, which restrict areas available for fishing, swimming and wading. These adverse effects related to water quality negatively influenced the quality of the recreational experience for visitors and also resulted in safety risks to the recreational visitors. **Because existing conditions for water-contact-based recreational activities are considered adverse due to water quality, improved water quality conditions would result in long-term beneficial effects.**

Dam removal could impede access for whitewater boating opportunities. Dam removal would not affect whitewater boating access locations, as access areas are at established areas along the Klamath River channel, outside of the subject reservoirs and would not be affected by dam removal. As discussed in the impact analysis above and in Section 3.11, Geology, Soils, and Geologic Hazards, drawdown of the reservoirs would not result in substantial changes to the floodplain or river channel. Thus, no impacts to land-based recreational facilities are expected. **Therefore, there would be no adverse impacts on whitewater boating access downstream from Iron Gate Dam.** However, in the reaches between the existing dams, particularly in the Hell's Corner Reach, whitewater boating access would likely be affected due to dam removal activities and sedimentation, as discussed previously. **Impacts in reaches between the existing dams would be short term and less than significant.**

Dam removal could increase the number of days with acceptable flows for various whitewater boating and recreational fishing in the Keno Reach and reaches downstream from Iron Gate Dam. The Lead Agencies modeled the average number of days providing acceptable river flows in specific reaches each month for specific recreational activities, both with and without dam removal (full modeling data is presented in Appendix R; DOI 2011). Table 3.20-16 presents a summary of the model results, and Figures 3.20-4 through 3.20-11 show the results for each of the river reaches. For the Keno Reach (see Figure 3.20-4) and the reaches downstream from Iron Gate Dam (Figures 3.20-8 through 3.20-11), the changes in the availability of flows within the acceptable flow ranges for whitewater boating and fishing opportunities would be negligible. However, as described in Section 3.20.3.2, existing difficult access to the Keno Reach, including a flat water paddle above J.C. Boyle Dam, currently limits recreational use of this area. Dam removal would likely improve access to the Keno Reach and would benefit whitewater boating and fishing opportunities in this area. **Given negligible changes in flows and improvements in access, there would be long-term beneficial effects on whitewater boating and fishing opportunities in the Keno Reach. Impacts in reaches downstream from Iron Gate Dam would be less than significant.**

Table 3.20-16. Estimated Number of Days Meeting the Range of Acceptable Flows for Recreational Activities on the Klamath River

River Reach	Activity	Acceptable Flow Range		Total Avg. No Days Annually		
		Low Value (cfs)	High Value (cfs)	Dams In	Dams Out	Percent Change
Keno Reach	Whitewater Boating	1,000	4,000	151	139	-7.9%
	Fishing	200	1,500	246	238	-3.5%
J.C. Boyle Bypass Reach	Whitewater Boating	1,300	1,800	5	41	793.6%
	Fishing	200	1,000	107	142	32.6%
Hell's Corner Reach	Whitewater Boating/Kayaking	1,000	3,500	332	189	-43%
	Whitewater Boating/Rafting	1,300	3,500	278	119	-57.1%
	Fishing	200	1,500	234	228	-2.7%
Copco 2 Bypass Reach	Whitewater Boating	600	1,500	10	223	2,083.8%
	Fishing	50	600	14	3	-79.4%
Iron Gate to Scott River	Whitewater Boating/Fishing	800	4,000	278	281	1.0%
Scott River to Salmon River	Boating	800	7,000	243	246	1.4%
	Fishing	800	4,000	175	182	4.2%
Salmon River to Trinity River	Whitewater Boating/Fishing	800	10,000	207	211	1.8%
Trinity River to Ocean	Whitewater Boating/Fishing	1,800	18,000	239	238	-0.2%

Key:

cfs: cubic feet per second

*Dam removal could increase the number of days with acceptable flows for whitewater boating and recreational fishing in the J.C. Boyle and Copco 2 Bypass Reaches. There would be a substantial increase in the availability of whitewater boating flows within the acceptable flow range for the J.C. Boyle Bypass Reach, particularly during the May through July time period. Based on the modeling results, under the dams out scenario, there would be a shift from the availability of acceptable fishing flows during July/August time period to March through May time period (see Figure 3.20-5 and Appendix R for full data). For the Copco 2 Bypass Reach there would be a substantial increase in whitewater boating opportunities during the July through September time period (see Figure 3.20-7 and Appendix R for full data) and a slight reduction in length of time for Copco 2 for fishing, primarily a reduction during May time period in the availability of acceptable flows. **Therefore, there would be long-term beneficial effects on whitewater boating in the J.C. Boyle and Copco 2 Bypass Reaches. In regards to fishing opportunities in these reaches, the impacts would be less than significant.***

Figure 3.20-4. Comparison of Available Recreation Flows - Keno Reach.

Figure 3.20-5. Comparison of Available Recreation Flows - JC Boyle Bypass Reach.

Figure 3.20-6. Comparison of Available Recreation Flows - Hell's Corner Reach.

Figure 3.20-10. Comparison of Available Recreation Flows - Salmon River to Trinity River Reach

Figure 3.20-11. Comparison of Available Recreation Flows - Trinity River to Ocean Reach

Dam removal could decrease the number of days with acceptable flows for whitewater boating in the Hell's Corner Reach. For the Hell's Corner Reach (see Figure 3.20-6), there would be loss of acceptable flows for whitewater boating opportunities as compared to existing conditions. For flows in the range of from 1000-3500 cfs there are modeled decreases of 49%, 58% and 35% respectively in the high demand months of July, August and September. Similarly, for flows from 1300-3500 cfs the reductions would be 36%, 88% and 76% for the same months (Recreation Sub-Team 2010; PacifiCorp 2004b; FERC 2007; Greimann 2012). See Appendix R.

Currently, the Hell's Corner Reach is the only Class IV+ rapids in the region with late summer flows. Whitewater rafters can boat on the Hell's Corner Reach from April through October due to hydroelectric peaking power and flows historically generated by J.C. Boyle Powerhouse to meet high power demand periods. In terms of fishing opportunities, there would be a reduction in the availability of acceptable flows during April; however, overall, the impacts would be minor. **Impacts on whitewater boating opportunities in the Hell's Corner Reach would be significant and unmitigable. Impacts on fishing would be less than significant.**

Dam removal could result in increased fisheries populations and abundance, which would improve recreational fishing along the river. As discussed in Section 3.3, Aquatic Resources, removal of the dams would improve habitat conditions for anadromous fish species and redband trout and is expected to result in increased populations of these species. The increased fisheries populations and abundance would beneficially affect recreational fishing opportunities. More specifically, the increased abundance and extent would allow for enhanced fishing opportunities and could decrease the number of closures of entire fishing seasons over the long term. Species specific analysis of the economic effects of increased recreational fishing is presented in Section 3.15, Socioeconomics. **These effects on recreation-based fisheries would be long term and beneficial.**

Implementation of Mitigation Measure REC-1 could permanently reduce recreational opportunities in the Klamath Basin. As described below in Section 3.20.4.4, Mitigation Measure REC-1 involves the development of a plan to develop new recreational facilities and river access points along the newly formed river channel between J.C. Boyle Reservoir and Iron Gate Dam following dam removal. However, replacement of recreation facilities would not necessarily be like for like but rather would be designed to accommodate a similar level but different type of use. This would require the creation of new gravel roads for vehicle and visitor access to the new recreation sites. While there would be a permanent loss of some recreation areas in the vicinity of the existing reservoirs, the combination of the implementation of REC-1 and the presence of regional recreation areas and opportunities (Table 3.20-4) would compensate for the loss of recreation areas at the subject reservoirs. **The impact from implementing Mitigation Measure REC-1, would be less than significant.**

3.20.4.3.4 Wild and Scenic River Assessment

The following section provides an assessment of the effects of Alternative 2 - full facilities removal on each of the four resources specified in the WSR Act Section 7(a) (fish, wildlife, scenery, and recreation river values). The following evaluation criteria were used to assess the effects of the proposed project as compared with conditions present at the time of WSR designation.

Evaluation Criteria for each of the four protected resources specified in the WSR Act Section 7 (a) (scenic, recreational, fish, and wildlife) criteria have been developed to assess the effects of the alternatives as compared with conditions at the date of the river's designation into the NWSRS (see Section 3.20.3.5 for conditions discussion). For each designated river component, the type (positive or negative) and duration (short term or long term) of the effects are described. The magnitude of these effects are analyzed in the Preliminary Section 7(a) Wild and Scenic Rivers Act Determination. The effects are characterized as unchanged, increased, or decreased (or similar conclusion), by value (scenic, recreational, fisheries, and/or wildlife), for that resource.

Scenery was evaluated using the following criteria:

- Water flow character (river flows and accompanying river width, depth and channel inundation or exposure)
- Water appearance (clarity, turbidity, depth of view, color, prominence of algae)
- Fish and wildlife viewing
- Riparian vegetation
- Natural appearing landscape character (the visual effects of facilities and structures as viewed from within the designated W SR corridor)

Recreation was evaluated using the following criteria:

- Whitewater boating
- Recreational fishing
- Other recreational activities (water play, swimming, camping)
- Recreational setting (water quality related aesthetic odors, tastes, contacts and public health and safety aspects)

Fishery was evaluated using the following criteria:

- Stream flow regime
- Water temperature
- Water quality (physical, biological and chemical)
- Aquatic habitat (geomorphic condition sediment transport regime and substrate quality)
- Fish species population conditions, specifically:
 - a. Anadromous salmonid fish species
 - b. Resident fish species
 - c. Species traditionally used and culturally important to Native Americans

Wildlife was evaluated using the following criteria

- Changes in habitat for affected species

Scenic Evaluation

Dam removal could result in changes to water flow character (river flows and accompanying river width, depth, and channel inundation or exposure) compared with conditions present when the Oregon Klamath WSR was designated as a National WSR. Short-term effects would result in a period of increased flows during the time of reservoir drawdown. The changed character of the river width would include areas of exposed substrate where water elevations recede. As modeled by Reclamation (see Section 3.6, Flood Hydrology), dam removal would eliminate the daily hydropower peaking releases with their associated large daily river level fluctuation (Reclamation 2012). This will reduce the appearance of sediment deposition and changes in turbidity and clarity of the water on a daily basis. River width and depth are defined by the geology of the region and the surrounding bedrock. As discussed in Section 3.11, Geology, Soils, and Geologic Hazards, river elevation and form downstream from J.C. Boyle dam are primarily controlled by large boulders and bedrock, and only limited adjustment is possible. As described in Section 3.20.3.5, above, the degree of visibility of these scenic quality effects is dependent on viewer location. Views from on-river, in-river, or riverside viewpoints are most likely to display changes to these scenic quality indicators, while views from river canyon roadways and communities are less likely to find these scenic quality changes to be as noticeable or substantial. **Therefore, for these reaches, the long-term scenic quality impacts would be positive due to the reestablishment of free-flowing water conditions.**

Dam removal could result in changes to water flow character (river flows and accompanying river width, depth, and channel inundation or exposure) compared with conditions present when the California Klamath WSR was designated. Downstream, in the California Klamath WSR, as discussed in Section 3.11, Geology, Soils, and Geologic Hazards, any substantial adjustment in river elevations or geomorphology would have already occurred in previous floods and no substantial changes to river morphology would occur following removal of the Four Facilities. Further, modeling conducted by Reclamation indicates that no long-term impacts would occur with regard to sediment deposition in pools, eddies, slack water, or beaches, and short term effects would be limited to the area immediately below Iron Gate Dam. **Free flowing river conditions as well as re-establishment of a more natural river channel would result in long-term scenic quality benefits for the California WSR component.**

Dam removal could result in changes to water appearance (clarity, turbidity, depth of view, color, and prominence of algae) compared with conditions present when the California and Oregon components were designated as National WSRs. As discussed in Section 3.2, Water Quality, removal of the PacifiCorp facilities would eliminate the major sources of water quality problems associated with the dams (i.e., the reservoirs). Removal of the dams and reservoirs would enhance downstream water appearance for the Oregon and California Klamath WSR scenery through its benefits of superior mixing and

oxygenation of waters upstream of the WSR, renewal of streambeds through more frequent, high flow flushing events, and reversal of suspected nutrient increases within J.C. Boyle, Copco 1, and Iron Gate Reservoirs. Section 3.2, Water Quality, provides a detailed discussion of improvements to water quality, including reduced floating algae, and increased water clarity. Although removal of the dams would likely result in short-term increases in turbidity and decreased water clarity due to high suspended sediment concentrations during the year following reservoir drawdown, particularly in the California Klamath WSR, long-term impacts would result in improved water appearance.

As discussed in Section 3.3, Aquatic Resources, spawning gravels released downstream from within the retired reservoirs would restore some natural sediment processes and contribute to scour of attached downstream algae. The deposited sand and gravel on the downstream reaches would be a less favorable habitat for the algae because of greater particle mobility during high-flow events. This would result in positive long-term impacts on scenic water appearance (improved clarity and algae reduction) within the river between Iron Gate Dam and the Shasta River confluence, and would likely have similar but reduced downstream benefits.

At the time of the Oregon Klamath WSR designation, the water appearance during summer base flow conditions was of slow-moving waters with large amounts of visible algae-covered rocks, and during peaking events the water appearance was altered to brown and murky colors with large quantities of algal foam. Information about scenery water appearance condition at the time of California Klamath WSR designation is lacking; however, it is likely that the trend of increasing habitat for attached algae with its associated water coloration, cloudiness, and limitations on depth of view was already underway at the time of WSR designation (Van De Water et al. 2006). Removal of the dams would restore natural sediment movement in the streambed and would reduce opportunities for algae attachment, to a degree not possible in 1981 and 1994 due to the presence of the Four Facilities. **Thus, while there would be short-term negative water clarity impacts on scenic quality due to turbidity and silt which could be exposed on river banks, long-term effects to scenic quality would be beneficial for both the California and Oregon Klamath WSR components.**

Dam removal could result in changes in opportunities for fish and wildlife viewing compared with conditions present when the California and Oregon Klamath WSRs were designated. As discussed in Section 3.3, Aquatic Resources, removal of the Four Facilities would increase the abundance of anadromous fish in the Klamath River. The potential restoration of the anadromous fish populations would largely be the result of the increase of anadromous fish habitat within the Upper Klamath Basin, along with water quality improvements within the Oregon and California Klamath WSRs downstream from the Four Facilities. The increased population of fish species would improve scenic fish viewing attractions in both the California and Oregon Klamath WSRs. Increased fish viewing would be most prominent during fish migration, spawning, or holding periods, when the fish concentrate at particular reaches, pools, riffles, and falls. **Fish and wildlife**

viewing impacts to scenic quality would be long-term and beneficial as compared to the conditions at the time of the 1981 and 1994 designations for the Oregon and California Klamath WSRs.

Dam removal could result in changes in opportunities for river-dependent wildlife viewing compared with conditions present when the California and Oregon Klamath WSRs were designated. Specific effects on river-dependent wildlife populations and scenic viewing opportunities are unknown. As discussed in Section 3.5, Terrestrial Resources, riparian habitat within the Oregon Klamath WSR and potentially beyond, in the Iron Gate Dam to Shasta River segment of the California Klamath WSR, would be improved by removal of the dams, and proportional increases in wildlife presence related to the increase in abundance of anadromous fish in the river and scenic wildlife viewing would be expected. **Therefore, impacts on river-dependent wildlife populations and scenic viewing opportunities would be long term and beneficial as compared to the conditions at the time of the 1981 and 1994 designations.**

Dam removal could result in changes to riparian vegetation compared with conditions present when the Oregon Klamath WSR was. As discussed in Section 3.5, Terrestrial Resources, removal of the Four Facilities would result in elimination of the reservoirs and associated aquatic habitat. However, following dam removal and downstream sediment flushing, the new river channel would conform to the pre-dam channel alignment (Gathard Engineering Consultants 2006). Riverbank stabilization and re-vegetation of riverbank with native plantings would be conducted at each reservoir after the drawdown is complete. Thus, riparian habitat at reservoirs would increase with restoration following drawdown. PacifiCorp estimated that decommissioning and removal of the Four Facilities would add about 184 acres of riparian vegetation. This estimate was based on the assumption of an average riparian corridor width of 100 feet along the 3.6-mile length of the J.C. Boyle Reservoir, the 4.5-mile length of the Copco Reservoir, the 0.3-mile length of the Copco 2 Reservoir, and the 6.8-mile length of the Iron Gate Reservoir (FERC 2007). **Establishment of woody species along the newly formed riparian corridor is expected to take several years; however, these changes to vegetation would result in long-term, beneficial effects on riparian vegetation aspects of scenic quality within the areas immediately upstream and downstream from the Oregon Klamath WSR component as compared to conditions at the time of the 1994 designation.**

Dam removal could result in changes to riparian vegetation compared with conditions present when the California Klamath WSR was designated. Removal of the Four Facilities would result in a more natural riparian vegetative community immediately downstream from Iron Gate Dam due to sediment deposition and scour and gravel transport. Improved riparian vegetation would increase the presence and scenic variety of the vegetation within the WSR. **This would likely increase overall scenic riparian vegetation aspects of scenic quality over conditions present at the California Klamath WSR's 1981 date of designation and result in long-term beneficial effects.**

*Dam removal could result in changes to the natural appearing landscape character as compared with conditions present when the Oregon Klamath WSR was designated. As discussed in Section 3.19, Scenic Quality, removal of J.C. Boyle Dam would result in a more natural setting and character in the areas immediately upstream and downstream from the Oregon Klamath WSR. **J.C. Boyle dam was present at the time of the 1994 WSR designation of the Oregon component, its removal would restore the Oregon Klamath WSR to a more natural flow regime and landscape character and would result in long-term beneficial scenic quality effects.***

*Dam removal could result in changes to the natural appearing landscape character as compared with conditions present when the California Klamath WSR was designated. The California Klamath WSR is downstream from the Four Facilities; therefore, removal of the dam and associated facilities would not result in any changes to the overall landscape character in this segment of the river. However, as discussed in Section 3.2, Water Quality, water clarity in the WSR component is expected to improve, as is the quality of the riparian vegetation. **These improvements would result in a more natural flow regime and landscape character for the California Klamath WSR and result in a long term positive scenic quality effect.***

Recreation Evaluation

*Dam removal could improve opportunities for whitewater boating compared with conditions present when the California and Oregon Klamath River WSRs were designated. Whitewater boating opportunities relating to river flow following removal of the Four Facilities would likely be similar to conditions in 1981 for the California Klamath WSR. As discussed in the impact analyses above, and as shown in Table 3.20-6 the number of days acceptable for commercial whitewater boating during the popular summer months would decrease for the Oregon Klamath WSR in the Hell's Corner Reach, following removal of the dams(Appendix R). For the California Klamath WSR downstream from Iron Gate Dam, following removal of the dams, the number of days available for whitewater boating would be very similar to the number of days currently available. **Therefore, long-term whitewater boating impacts due to changes in flow would be negative for the Oregon Klamath WSR. No impacts to whitewater boating opportunities due to flow would occur for the California Klamath WSR. Removal of the dams would also result in long-term improvements to water quality conditions over existing conditions and the 1981 and 1994 conditions. With improved water quality, the whitewater boating recreation experience would improve in both the Oregon and California Klamath WSRs. Therefore, long-term whitewater boating impacts due to improved water quality would be beneficial for both the California and Oregon WSR components.***

Dam removal could increase opportunities for recreational fishing compared with conditions present when the California and Oregon Klamath River WSRs were designated. As discussed in the impact analyses above, removal of the Four Facilities would not affect water flow such that days with acceptable flows for recreational fishing would substantially increase or decrease. However, as described in Section 3.3, Aquatic Resources, the geographic extent of the Klamath River fish habitat would be substantially

expanded compared to 1981 and 1994 conditions. It is also expected that water quality conditions would improve, thereby reducing fish disease. Increased fish populations would likely result in fewer catch and keep fishing restrictions. **Thus, recreational fishing impacts would be long term and beneficial for both the California and Oregon WSRs.**

Dam removal could result in changes to opportunities for other recreational activities (water play, swimming, camping) compared with conditions present when the California and Oregon Klamath River components were designated as National WSRs. During the period of dam removal and shortly afterwards, sediment release could decrease the quality of water contact activities. However, initial reservoir drawdown will occur in the coldest high flow months of winter and early spring when recreation uses is at its lowest. This impact would be short term. In the long term, dam removal would improve water quality and thus water contact-based recreation activities. Short-term, negative impacts would occur as a result of the construction activities and staging areas and likely restricted access and use of recreation facilities and opportunities during the period and in the areas where dam removal occurred. **Thus for the Oregon Klamath WSR there would be short term negative impacts to other recreational activities due to construction activities and increased sediment in the river. In the long term dam removal would be long term and beneficial as compared to the 1994 conditions. For the California Klamath WSR, dam removal would not affect recreational activities access downstream from the dams. However dam removal would result in improved water quality in the long term thus there would be long-term beneficial effects on recreational activities in these areas as compared to the 1981 conditions.**

Dam removal could improve the recreational setting (water-quality related aesthetics, odors, tastes, contacts, and public health and safety aspects) compared with conditions present when the California and Oregon Klamath WSRs were designated. Although there would be short-term, negative impacts on water quality due to the increased sediment load in the river during initial drawdown activities, particularly in the Oregon Klamath WSR, as discussed in Section 3.2, Water Quality, following completion of reservoir drawdown, dam removal would improve water quality conditions as compared with conditions present at the time of the 1981 and 1994 designations. There could be short-term, negative impacts (lasting less than two years) during reservoir drawdown due to the potential for sediment to clog fishing holes, or possibly make the river less navigable, or even less accessible along shorelines temporarily blocked by sediment deposits.

Alternatively, new beaches and riparian areas may become established to increase the variety of shoreline settings. Most of these effects would be temporary and many aspects of the WSR's recreation setting would be considerably improved once the river stabilizes. The improved water quality conditions following completion of drawdown activities would improve the recreational setting overall (i.e., with improved clarity during swimming and fishing and reduced malodors and tastes [Bartholow et al 2005]). With regard to public health, improved water quality would also reduce potential human health

risks associated with water-contact-based activities. **Therefore, impacts on the recreational setting would be long term and beneficial for both the California and Oregon Klamath WSR.**

Fisheries Evaluation

Dam removal could alter stream flow regime compared with conditions present when the California and Oregon Klamath WSRs were designated. Section 3.6, Flood Hydrology, discusses historic flow rates and discharge statistics for each of the reservoirs. The proposed drawdown rates are consistent with the historic discharge rates from the reservoirs and would be adjusted depending on the water year; therefore, flow rates downstream from the dams are not anticipated to increase substantially above historic rates, if at all. As such, conditions during the drawdown period are expected to remain largely unchanged as compared to stream flow regimes at the time of the 1981 and 1994 designations.

Following removal of the Four Facilities, the Klamath River would return to a natural flow regime in the reaches where the reservoirs currently exist. Restoration of the natural flow regime would improve water quality conditions, likely reducing the occurrence of myxozoan parasites (*Ceratomyxa shasta* and *Parvicapsula minibicornis*) that are known to negatively affect salmonids. Removal of the hydroelectric reservoirs would eliminate populations of blue-green algae that produce toxins that can result in acute and chronic effects on fish, including increased mortality, reduced fecundity, reduced feeding, and habitat avoidance. **Stream flow regime impacts would be long term and beneficial for both the California and Oregon Klamath WSR.**

Dam removal could decrease fall water temperature and increase spring water temperature compared with conditions present when the California and Oregon Klamath WSRs were designated. Removal of the Four Facilities would improve water quality conditions over existing conditions and the 1981 and 1994 conditions. As described in Sections 3.2, Water Quality, and 3.3, Aquatic Resources, following dam removal, the temperature regime downstream from Iron Gate Dam would be more suitable for salmon. As part of its relicensing procedure, PacifiCorp modeled changes in water temperature that could result following removal of the dams. The modeling results show that from Iron Gate Dam to Clear Creek temperatures in the spring and early summer would be as much as 5°C warmer, but cooler in later summer and fall than under existing conditions. Temperatures currently remain greater than 20°C in dry years with little variability in July and August. Although summer temperatures would likely be more variable following dam removal, the median temperatures would be substantially lower than current conditions. Summer and fall temperatures would therefore be more conducive to salmon rearing, migrating, and spawning than the conditions that were probable at the date of designation (Van de Water et al. 2006). However, as discussed in Section 3.2, Water Quality, in reaches above J.C. Boyle Reservoir and downstream from Clear Creek, there would be little to no change in the existing temperature regime. **Water temperature impacts would therefore be long term and beneficial for the California Klamath WSR, and there would be no change from existing conditions in the Oregon Klamath WSR.**

Dam removal could improve water quality characteristics (physical, biological, and chemical) compared to conditions present when the California and Oregon Klamath WSRs were designated. Removal of the Four Facilities would eliminate the major sources of water quality problems in the Upper Klamath Basin and enhance downstream water quality for salmonids. Removal of the dams would also reduce conditions that foster fish disease outbreaks.

As discussed in Section 3.2, Water Quality, following dam removal, long-term dissolved oxygen levels would be anticipated to meet applicable Basin Plan objectives. However, modeling indicates that nitrogen loading downstream from Iron Gate Dam would increase slightly above existing levels due to the release of sediments from the reservoirs, but the removal of a lacustrine environment in the reservoir area would reduce the abundance of algae that form habitat for the intermediate host for at least two salmon pathogens. The improved water quality conditions would reduce fish crowding, which, as discussed in Section 3.3, Aquatic Resources, would result in reduced temperature-induced stress and could allow for spawning to begin earlier in the fall. **Impacts on water quality characteristics would therefore be long term and beneficial for both the California and Oregon Klamath WSRs.**

Dam removal could alter geomorphic conditions, sediment transport regime, and substrate quality compared with conditions present when the California and Oregon Klamath WSRs were designated. As discussed in Section 3.11, Geology, Soils, and Geologic Hazards, and Section 3.3, Aquatic Resources, sediment stored in the subject reservoirs would be released downstream. The released sediment would have short-term, negative effects on aquatic habitat, but following completion of reservoir drawdown, the increased spawning gravel released from upstream could enhance spawning habitat. Restoring natural sediment processes would contribute to scour of attached algae (e.g., *Cladophera* spp.), and deposited sand and gravel would be a less favorable substrate for the algae because of greater particle mobility during high-flow events than the existing armored substrate. A reduction in such algae would lead to reduced habitat for the fish pathogen's alternate host.

Information about habitat conditions at the time of WSR designation is lacking; however, it is likely that trends of river coarsening, increasing habitat for attached algae, and reduced recruitment and maintenance of riparian vegetation were already underway at the time of WSR designation due to PacifiCorp facilities and operations. The Proposed Action would reduce those trends in the long term, and restore natural sediment transport processes, which were no longer in place by 1981 and 1994. Following the initial drawdown period and flushing of reservoir sediment downstream, aquatic habitat conditions would be expected to be improved from conditions in 1981 and 1994 in the long term. **Therefore, impacts on aquatic habitat conditions would be long term and beneficial for both the California and Oregon Klamath WSRs.**

Dam removal could improve conditions for anadromous fish species compared with conditions present when the California and Oregon Klamath WSRs were designated. As discussed in Section 3.34.3.2.2.3, Aquatic Resources, dam removal would result in

beneficial long-term effects on anadromous salmonids. Dam removal would also restore connectivity to hundreds of miles of potentially usable habitat in the Upper Klamath Basin and would create additional spawning and rearing habitat within the Hydroelectric Reach. However, sediment released during dam removal could be sufficient to cause substantial smothering of spawning gravels, pool infilling, gill abrasion, and changes to holding and migration patterns in the river reaches immediately below Iron Gate Dam. These impacts would be short term (lasting less than two years), as sediment is expected to be flushed through the river system relatively quickly. In the long term, dam removal is expected to eliminate the source of most of the water quality issues on both the California and Oregon Klamath WSRs that are influenced by the presence of the PacifiCorp facilities. In particular, dam removal would reduce late summer and fall heating, summertime dissolved oxygen depletion, and in-reservoir nutrient cycling with resultant summer releases of nitrogen downstream. Removal of the Four Facilities would also eliminate a fish barrier and allow fish to spawn in a greater number of areas. Consequently, fish disease outbreaks could be diminished. Removal of the Four Facilities would also result in habitat conditions that more closely resemble natural conditions (e.g., flow and temperature ranges would be more reflective of climatic forces than of water regulation). However, continuation of the operation of the Iron Gate Fish Hatchery would reduce some of the beneficial effects of dam removal by continuing pressures on natural stocks that would improve with dam removal. Even so, Chinook salmon, coho salmon, and steelhead abundance would still be expected to increase over 1981 and 1994 levels in the long term. **Long-term beneficial effects on conditions for anadromous fish species would result for both the California and Oregon Klamath WSRs.**

Dam removal could improve conditions for native resident fish species compared with conditions present when the California and Oregon Klamath WSRs were designated. As discussed in Section 3.3, Aquatic Resources, removal of the Four Facilities would improve conditions for native resident fish species by restoring connectivity between the Lower and Upper Klamath River, and by returning a natural flow regime to the reaches where the reservoirs currently exist, thereby improving water quality. Dam removal would also likely result in diminished non-native fish habitat and populations, reducing competition for space and resources with native resident fish. Because the non-native fish were introduced and occur in other nearby water bodies, their loss would not be considered significant from a biological perspective and is not included in this effect evaluation. **Therefore these impacts on the conditions for native resident fish species would be long term and beneficial in both the California and Oregon Klamath WSRs.**

Dam removal could improve conditions for species traditionally used and culturally important to Indian Tribes compared with conditions present when the California and Oregon Klamath WSRs were designated. As discussed in Section 3.3, Aquatic Resources, removal of the Four Facilities would improve conditions for culturally important fish species (e.g., Chinook salmon, coho salmon, steelhead, and lamprey) by restoring connectivity between the Lower and Upper Klamath River, and by returning a

natural flow regime to the reaches where the reservoirs currently exist and downstream from Iron Gate Dam, thereby improving water quality. Dam removal would also likely result in diminished non-native fish habitat and populations, reducing competition for space and resources with native resident fish. **Impacts on the conditions for species traditionally used and culturally important to Indian Tribes would be long term and beneficial in both the California and Oregon Klamath WSRs.**

Wildlife Evaluation

Dam removal could result in changes to habitat for special status species compared with conditions present when the California and Oregon Klamath WSRs were designated. Elimination of hydropower peaking flows in the Oregon Klamath WSR would result in beneficial establishment of riparian vegetation over the long term due to fine sediment released into this section would allow the establishment of such vegetation.

Riparian vegetation in the California Klamath WSR downstream from the Iron Gate Dam would also benefit from dam removal, especially in the reach between the Iron Gate Dam and the Shasta River confluence. Special status species that are dependent on riparian habitat, such as the willow flycatcher, northwestern pond turtle, and yellow breasted chat, would benefit greatly from successful riparian habitat recovery from Iron Gate Dam downstream to the Klamath River's confluence with the Shasta River. Downstream from that point, the riparian-dependent wildlife would still benefit from increased diversity and amounts of riparian vegetation, but these benefits might be offset by some potential short-term impacts as the released sediment moves downstream into areas that are currently in better condition.

In addition to improving riparian habitat, the Proposed Action would result in improvements in fish resources in the long term following dam removal, thus providing increased forage for wildlife species that depend upon fish as a food source. The area currently blocked by dams would provide additional available habitat for anadromous fish. The increase in habitat quality and quantity should allow the number of anadromous fish to increase substantially. Increased numbers of fish would also create greater foraging opportunities for riparian and riverine species such as bald eagle, river otter, osprey and black bear. **Therefore, there would be long-term, beneficial effects on habitat for special status species in both the California and Oregon Klamath WSRs.**

3.20.4.3.5 Eligible and Suitable WSR Section on the Klamath River

In addition to the designated WSR segments, the reach from the Oregon and California State-line to Copco was found eligible and suitable and is a candidate for WSR designation, but has not been designated into the National WSR System. The potential outstandingly remarkable values are scenic, fish, wildlife, recreation (whitewater boating and fishing), and historic. This candidate WSR reach is included in the project area and effects are evaluated as part of this EIS. This section summarizes the main effects of the Proposed Action on this segment's river values. Short term negative effects on water quality, scenic, recreation, fishery, and wildlife river values are likely due to the high suspended sediment concentrations during reservoir drawdown. These effects are expected to last less than two years. In the long term, dam removal would return this

reach of river to a more natural river flow, improve water quality, enhance habitat for fish and wildlife, and restore riparian vegetation. **Thus, dam removal would result in long-term beneficial effects to this candidate WSR reach's free-flowing condition, water quality, scenic, wildlife, fishery, and recreation river values.**

Keno Facilities Transfer

Transfer of the Keno Facility from PacifiCorp to DOI could affect recreational opportunities. Keno Dam is an unmanned facility which requires minimal operations and maintenance. Recreation facilities owned by PacifiCorp in the vicinity of Keno Impoundment/Lake Ewauna will also be transferred to DOI as described in the KHSA Section 7.5. Operation of Keno Dam and of the recreation areas are expected to continue in their current fashion. **The transfer of the facility and recreation lands will result in no change from existing conditions.**

East and Westside Facilities Decommissioning – Programmatic Measures

The decommissioning of the East and Westside Facilities could have adverse effects on recreational resources. Decommissioning of the East and Westside canals and hydropower facilities of the Link River Dam by PacifiCorp as a connected action to the Klamath Hydroelectric Settlement Agreement (KHSA) would terminate the diversion of water flows currently diverted at Link River Dam into the two canals. Following decommissioning of the facilities there will be no change in outflow from Upper Klamath Lake or inflow into Keno Impoundment/Lake Ewauna. **Therefore, there will be no change from existing conditions caused from decommissioning the East and Westside Facilities.**

City of Yreka Water Supply Pipeline Relocation – Programmatic Measures

The City of Yreka Water Supply Pipeline, currently under the Iron Gate Reservoir, would need to be relocated to avoid damage after the reservoir is removed, creating a change in existing recreational resources. As a connected action to the Proposed Action, the relocation, replacement, and/or burial of the existing 24-inch diameter water line and transmission facilities from the City of Yreka's Fall Creek diversion would be required (KHSA Section 7.2.3). This connected action would involve placing the City of Yreka's waterline on a pipe bridge across the river. This would require construction of footings and other infrastructure to support the pipe bridge, resulting in construction at the site. The relocation of the pipeline would not impact recreational resources. In coordination with the City of Yreka, measures such as installation of fencing to protect the water supply intake maybe considered. **There would be no change from existing conditions.**

Another option under consideration is to place the pipeline along the Lakeview Bridge at Iron Gate Dam rather than creating a new span for the pipeline. The pipe would be relocated from its current route and cross the river along the underside of the bridge. Surveys are still required to determine if the bridge is adequate to support the pipeline and the construction traffic from the decommissioning activities. This option would not affect recreational resources. **There would be no change from existing conditions as a result of the Proposed Action and pipeline relocation.**

3.20.4.4 KBRA – Programmatic Measures

The Klamath Basin Restoration Agreement (KBRA) has several programs that could result in short-term and long-term changes to recreational opportunities in the Klamath Basin. Such changes would be the result of temporary construction activities as well as long-term increases in aquatic habitat and fish populations, improvements to water quality, and improvements to terrestrial resources. Specific KBRA programs potentially affecting recreational opportunities include:

- Phases I and II Fisheries Restoration Plans
- Fisheries Reintroduction and Management Plan
- Wood River Wetland Restoration
- Water Diversion Limitations
- On-Project Plan
- Water Use Retirement Program (WURP)
- Climate Change Assessment and Adaptive Management
- Interim Flow and Lake Level Program

Construction activities associated with the KBRA programs could temporarily restrict access to recreational opportunities. Construction activities including channel construction, fish passage and facilities construction, breaching levees, and fish hauling would likely involve the use of heavy equipment along floodplain and riparian areas and therefore could result in restrictions to public access for recreational activities, such as sightseeing, bank fishing, swimming, and wading. Because restoration activities would occur throughout the entire basin, specific sections of the river could be closed for a period of time throughout implementation of the KBRA programs. However, as described in the Affected Environment section, there are a number of recreational areas offering similar activities and settings throughout the basin. It is likely that for any particular project, there would be an alternative recreational area nearby that could be used during temporary closures. Construction related to KBRA programs could occur in the same location and time as construction actions for the hydroelectric facility removal and affect access to or availability of recreation resources. However, because of the multitude of resources in the region, effects to recreation under both the KBRA and KHSA would be less than significant. **Thus, potential impacts to recreational opportunities are anticipated to be less than significant. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

Construction activities associated with KBRA programs could result in short-term water quality impacts which could affect recreational opportunities. Erosion and sedimentation during construction activities has the potential to temporarily decrease water quality and reduce water visibility for boaters, swimmers, and fisherman. These short-term water quality impacts would be anticipated to occur throughout the basin where construction activities take place. Specific sections of the river could be affected for a period of time throughout implementation of the KBRA programs. However, following implementation and related construction activities for KBRA programs including the Wood River

Wetland Restoration, and the Interim Flow and Lake Level Program, WURP, water quality and clarity would be expected to improve. Additionally, as described above, short-term impacts would be offset by the ability of visitors and local recreationalists to use the recreational areas with similar activities and settings throughout the basin.

Construction related to KBRA programs could occur in the same location and time as construction actions for the hydroelectric facility removal and affect water quality at recreation resources. However, because of the multitude of resources in the region, effects to recreation under both the KBRA and KHSR would be less than significant.

Potential impacts would be short term and, with implementation of construction BMPs, are anticipated to result in less than significant water quality related recreational impacts. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.

Fire treatment proposed in the Fisheries Restoration Plan could alter the visual setting and result in decreased recreational visitors to the Klamath Basin. As described above for the No Action/No Project Alternative, it is expected that landscape scale prescribed fire treatments would result in a short-term adverse effect of the visual quality of the burned area, which could directly affect the number of recreational visitors to the area. In the short term, prescribed fire treatments would be less than significant. Prescribed fire treatment actions would not occur in the same location and at the same time as hydroelectric facility removal actions; therefore, potential for any visual quality improvements generated by these prescribed fire treatment actions would not change effects of facility removal. **The return of forests to a more natural condition is anticipated to result in long-term beneficial effects. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

KBRA actions correcting fish passage issues, reintroducing and monitoring fish species, and restoring aquatic habitat could increase recreational fishing and wildlife viewing opportunities in the basin. It is expected that correction of fish passage issues throughout the basin would restore fish access to new and historic habitats and result in increased fish populations. KBRA programs such as the Fisheries Reintroduction and Management Plan, include actions to restore and create fish habitat and wetlands for endangered fish species. Additionally, projects such as Water Diversion Limitations would increase water availability for fisheries. It is anticipated that these programs and projects would result in increased fish populations and abundance, which would beneficially affect recreational fishing opportunities. More specifically, the increased abundance would allow for increased catch limits and fewer catch and release requirements, as well as decrease the potential of closures of entire fishing seasons as those that occurred on the Klamath River in the recent past. Correction of fish passage issues as a result of the KBRA would support the positive improvements to recreation from increased fish populations due to hydroelectric facility removal. **These changes are anticipated to result in beneficial effects to recreational experiences throughout the Klamath Basin. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

KBRA programs resulting in long-term water quality improvements could increase recreational opportunities throughout the Klamath Basin. KBRA programs including the Fisheries Restoration Plans Phase I and II; Fisheries Reintroduction and Management Plan; WURP; and, Interim Flow and Lake Level Program would result in long-term benefits to water quality throughout the Klamath Basin. As described in Section 3.2, Aquatics Resources, improvements in water quality would enhance fisheries habitat in the Klamath River and tributaries. Improvement of water quality as a result of KBRA actions would support positive improvements to recreation from improved water quality due to hydroelectric facility removal. **It is anticipated that improvements in fish habitat and abundance would result in beneficial effects to recreational opportunities in the Klamath Basin. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

KBRA programs that enhance terrestrial wildlife and plant resources could increase recreational opportunities throughout the Klamath Basin. KBRA programs including Fisheries Restoration Plans Phase I and II; Water Diversion Limitations; On-Project Plan; WURP; and, Interim Flow and Lake Level Programs would result in long-term benefits to terrestrial species as a result of restored floodplain and riparian vegetation and habitat areas. While short-term construction activities involved in the implementation of some of these programs would result in short-term adverse impacts on terrestrial resources, the long-term effects of habitat restoration would be expected to benefit terrestrial species in the Klamath Basin. Improvement of terrestrial wildlife and plant resources as a result of the KBRA would support positive improvements to wildlife viewing due to hydroelectric facility removal. **It is anticipated that improvements and increases in terrestrial wildlife habitat would result in beneficial effects to recreational wildlife viewing and recreational hunting opportunities in the Klamath Basin. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

3.20.4.4.1 Alternative 3: Partial Facilities Removal of Four Dams

Under this alternative, short-term demolition activities and drawdown of reservoirs would still occur; however, demolition would consist only of in-stream facilities and select ancillary facilities; other ancillary facilities associated with the KHP would remain in place. Recreation facilities would be removed with the exception of Topsy Campground, Fall Creek and Jenny Creek Day Use Areas, and the Iron Gate Fish Hatchery Day Use area, as under the Proposed Action and the impact would therefore be the same as described previously.

Keno Facilities Transfer

Transfer of the Keno Facility from PacifiCorp to DOI could affect recreational opportunities. Keno Dam is an unmanned facility which requires minimal operations and maintenance. Recreation facilities owned by PacifiCorp in the vicinity of Keno Impoundment/Lake Ewauna will also be transferred to DOI as described in the KHS Section 7.5. Operation of Keno Dam and of the recreation areas are expected to continue

in their current fashion. **The transfer of the Keno Facility and recreation lands would result in no change from existing conditions in relation to recreational resources or facilities.**

East and Westside Facilities Removal – Programmatic Measures

The decommissioning of the East and Westside Facilities could have adverse effects on recreation. The effects of the East and Westside Facilities removal would be the same as those described for the Proposed Action. **Therefore, the decommissioning activities would result in no change from existing conditions in relation to recreation resources or facilities.**

City of Yreka Water Supply Pipeline Relocation – Programmatic Measures

The City of Yreka’s Water Supply Pipeline would need to be relocated to avoid damage after the removal of Iron Gate Reservoir; this action could create a change in existing recreational resources. The effects of relocating the City of Yreka’s Water Supply Pipeline would be the same as those described under the Proposed Action. **There would be no change from existing conditions.**

KBRA – Programmatic Measures

Under this alternative the KBRA would be fully implemented; therefore, impacts on recreation facilities and opportunities would be the same as described for KBRA under the Proposed Action.

Wild and Scenic Rivers

With regard to WSRs, impacts would be similar as for the Proposed Action.

3.20.4.4.2 Alternative 4: Fish Passage at Four Dams

The Fish Passage at Four Dams Alternative could change existing recreation access and opportunities. Impacts under this alternative would be similar to those described under the No Action/No Project Alternative. Because the dams would remain in place, none of the expected beneficial changes to water quality would occur; therefore, beneficial effects with regard to water-contact-based activities described under the Proposed Action would not occur. The recreational setting (campgrounds, day use areas, and water access areas) would remain as described in the Affected Environment section. **Under the Fish Passage at Four Dams Alternative, existing conditions for recreational fishing within the river and water-contact-based activities at the subject reservoirs would not change from existing conditions.**

Implementation of the prescriptions provided by the USFWS, DOI, and United States Department of Commerce in the FERC 2007 EIS could change whitewater boating opportunities in the Hell’s Corner Reach. There would be a loss of acceptable flows for whitewater boating opportunities in the Hell’s Corner Reach as compared to existing conditions. The prescriptions set minimum streamflow requirements for the Peaking Reach downstream from J.C. Boyle Powerhouse. A minimum streamflow of 1,500 cfs must be provided no more than once per week as opposed to existing conditions where acceptable whitewater flows are maintained a majority of days. In addition, there would

no longer be predictable flows in terms of known timing for flow releases as under the existing conditions. **Impacts on whitewater boating opportunities in the Hell's Corner Reach would be significant and unavoidable.**

Fish passage facilities could result in increased fisheries populations and abundance, which could improve recreational fishing along the river. As discussed in Section 3.3, Aquatic Resources, installation of fish passage at the dams would likely beneficially affect anadromous fisheries in the Klamath River, although not to as great a degree as under the Proposed Action. Increased abundance and population of recreational fishery species would likely result in beneficial effects on recreational fishing downstream from Iron Gate Dam. More specifically, the increased abundance would allow for increased catch limits and fewer catch and release requirements, and would decrease the number of potential fishing season closures such as those that occurred on the Klamath River in the recent past. Species specific economic analysis of the effects of increased recreational fishing is presented in Section 3.15, Socioeconomics. **Impacts with regard to recreational fishing opportunities would be long term and beneficial.**

3.20.4.4.3 Alternative 5: Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate

Dam removal could permanently remove recreational facilities in the area of Copco 1 and Iron Gate Reservoirs. Under this alternative, Copco 1 and Iron Gate Dams would be removed, but Copco 2 Dam and J.C. Boyle Dam would remain in place. The impacts would be similar to those described for the Proposed Action for the areas surrounding the Copco 1 and Iron Gate Reservoirs; recreation facilities at these sites would be removed. **Impacts on recreational facilities at Copco 1 and Iron Gate reservoirs would be considered permanent and significant; however, implementation of Mitigation Measure REC-1 would reduce these impacts in the long term to less than significant.**

Dam removal could permanently decrease the availability of reservoir/lake-based recreational opportunities. Reservoir-based recreational opportunities (e.g., swimming, bathing, wading, and reservoir-fishing) would be lost at Iron Gate and Copco 1 Reservoirs, although visitors would still be able to travel to J.C. Boyle Reservoir for these activities; thus, adverse impacts would be fewer and smaller in scale than those described for the Proposed Action. **Impacts on the regional availability of reservoir-based recreational opportunities would be less than significant.**

Dam removal could change whitewater boating opportunities in the Klamath River. With regard to changes in whitewater boating opportunities, the existing Copco 1 and Iron Gate Reservoirs would be converted to free-flowing riverine reaches over the long term, and depending on the river channel and access, could provide additional opportunities for whitewater boating in these reaches (Appendix R). However, as noted under the Proposed Action impact analysis, flows following dam removal were not modeled for areas currently inundated by reservoirs. While it could be expected there would be additional opportunities for whitewater boating in these reaches, no records exist of the condition or suitability of the presently inundated areas for whitewater boating activities. With details of the condition of these areas lacking, it is too

speculative to determine the quality and quantity of whitewater boating opportunities that could be realized due to dam removal in areas currently inundated by reservoirs. **Thus, while new whitewater boating opportunities would likely exist in the areas previously inundated by the reservoirs, impacts would be less than significant.**

Loss of peaking flows in the J.C. Boyle Peaking Reach could affect whitewater boating opportunities in the Hell's Corner Reach. The loss of peaking flows in the Hell's Corner Reach would result in the river returning to natural flow conditions, with no ability to regulate for peaking flows. Thus, there would be diminished whitewater boating opportunities in this reach. **Impacts on whitewater boating opportunities in the Hell's Corner Reach would be significant and unmitigable.**

Changes in water quality associated with dam removal could positively affect water-contact-based recreational opportunities. As discussed in Section 3.2, Water Quality, improvements in water quality are expected; however, these improvements would be less than as described under the Proposed Action. Therefore, beneficial effects on water-contact-based recreation would occur as described for the Proposed Action, in the river channel below Copco 1 Dam. Beneficial effects would not be anticipated to occur in or below the J.C. Boyle Reservoir (as described above, there are little to no recreational facilities at Copco 2 Reservoir). Also, as discussed in Section 3.3, Aquatic Resources, populations and abundance of anadromous fish would increase under this alternative (although not to the same degree described for the Proposed Action); therefore, beneficial effects on recreational fishing would be similar, but less than those described for the Proposed Action. **Because existing conditions for water-contact-based recreational activities are considered adverse due to water quality, improved water quality conditions would result in long-term beneficial effects.**

City of Yreka Water Supply Pipeline Relocation – Programmatic Measures

The City of Yreka's Water Supply Pipeline would need to be relocated to avoid damage after the removal of Iron Gate Reservoir; this action could create a change in existing recreational resources. The effects of relocating the City of Yreka's Water Supply Pipeline would be the same as those described under the Proposed Action. **There would be no change from existing conditions.**

3.20.4.5 Mitigation Measures

3.20.4.5.1 Mitigation Measure by Consequences Summary

REC-1 – At least one year before starting dam removal activities, the dam removal entity (DRE) will prepare a plan to develop new recreational facilities and river access points along the newly formed river channel between J.C. Boyle Reservoir and Iron Gate Dam. The purpose of the plan is to mitigate for recreational facilities that will be removed during dam removal. The intent is to provide resources and infrastructure which will support similar levels yet different types of use. The plan will be developed in consultation with appropriate State and Federal agencies, counties (e.g., BLM, CDFG,

Siskiyou and Klamath Counties) and stakeholder groups, and will include an implementation schedule for construction of recreational facilities and river access areas.

3.20.4.5.2 Effectiveness of Mitigation in Reducing Consequences

Implementation of Mitigation Measure REC-1 will ensure that access to the Klamath River at and near the location of the removed reservoirs will remain available following dam removal. The potential for fewer recreational opportunities than currently exist would be less than significant (See Section 3.20.4.3)

3.20.4.5.3 Agency Responsible for Mitigation Implementation

The DRE would be responsible for implementing mitigation measure REC-1.

3.20.4.5.4 Remaining Significant Impacts

Changes in flows in the Hell's Corner Reach and decreases in whitewater boating along this part of the river would be a significant and unavoidable impact.

3.20.4.5.5 Mitigation Measures Associated with Other Resource Areas

Mitigation Measures AR-1, 2, 5-7 could interfere with river based recreation downstream from Iron Gate Dam. These mitigation measures involve trap and haul of fish and mollusks to protect them from the reservoir drawdown and dam deconstruction activities. These mitigation measures would include trapping activities in the Klamath River that could interfere with river based recreation between February and April 2020. However, as described in Section 3.20.3.1, Regional Opportunities, a number of other river recreation areas are present within and adjacent to the Klamath Basin and provide similar opportunities for recreational activity. **Temporary impacts on recreational access from Mitigation Measures AR-1, 2, 5-7 would be less than significant.**

Mitigation Measure TR-1 could interfere with reservoir based recreation in Iron Gate Dam. The bridge crosses Jenny Creek at the point it enters Iron Gate Reservoir. Relocation of the Jenny Creek Bridge and culverts would occur before the other construction phases of dam removal. In comparison to the dam removal, equipment and time required for this construction would be minimal, but it could affect reservoir based recreation near the bridge. However, it will not restrict reservoir based recreation in other areas of the reservoir from other access points. **Impacts on recreational access from Mitigation Measure TR-1 would be less than significant.**

3.21 Toxic/Hazardous Materials

This section describes impacts related to the presence and/or use of hazardous, toxic, and radiological waste (HTRW) within the area of analysis for the Proposed Action and alternatives.

3.21.1 Area of Analysis

The area of analysis includes the area in the immediate vicinity of Keno, J.C. Boyle, Copco 1, Copco 2, and Iron Gate Dams, including their associated reservoirs, and areas identified as construction/demolition and staging areas for the alternatives. This section also addresses impacts related to HTRW at a programmatic level within the Klamath Basin Restoration Agreement (KBRA) area of analysis because specific locations of potential construction sites have not been identified.

3.21.2 Regulatory Framework

Hazardous materials, substances, and waste within the area of analysis are regulated by several Federal, State, and local laws and policies, which are listed below.

3.21.2.1 Federal Laws, Authorities and Regulations

- Resource Conservation and Recovery Act (42 USC 6901 et seq.)
- Hazardous Materials Transportation Act (49 USC Section 1801 et seq.)
- Clean Water Act (33 USC 1251 et seq.)
- Comprehensive Environmental Response Compensation and Liability Act and Superfund Amendment Reauthorization Act (43 USC 9601 et seq.)
- 40 CFR 260-279 Federal Regulations on hazardous waste management
- 42 USC 11001 et seq. Emergency Planning and Community Right to Know Act
- Toxic Substances Control Act (15 USC 2601 et seq.)

3.21.2.2 State Laws, Authorities and Regulations

- California Hazardous Waste Control Law (California Health and Safety Code [HSC] Section 25501 et seq.)
- Carpenter-Presley-Tanner Hazardous Substances Account Act (HSC Section 25300 et seq.)
- Unified Hazardous Waste and Hazardous Materials Management Regulatory Program (HSC Section 25404 et seq.)
- Solid Waste Management (Oregon Revised Statute [ORS] 459, and Oregon Administrative Rule [OAR] 340-093)
- Hazardous Waste and Hazardous Materials (ORS 465 and 466, and OAR 340 Divisions 100 to 106, 109, 111, 113, 120, 124, 135, and 142)
- General Environmental Quality (ORS 468, 468a, and 468b)

3.21.3 Affected Environment/Environmental Setting

3.21.3.1 Sites with Potential HTRW Concerns

As described in Section 3.21.4.1, Effects Determination Methods, a database search was conducted by consultant Environmental Data Resources (EDR) of sites within a 1-mile radius of the area of analysis where there is potential concern for the presence of HTRW (EDR 2010a and 2010b). Potential HTRW sites included spill sites, sites with leaking underground storage tanks, emergency response to releases sites, brownfields (urban development sites previously built upon), hazardous material incidents, and voluntary cleanup sites, among others. No recorded reviews or site inspections were performed on these sites identified from the database searches. Four potential HTRW sites within the area of analysis were identified by the EDR search. Two of the listings only indicated the presence of underground and aboveground storage tanks at the Copco Lake Store and the “Pacific Power – Iron Gate,”; but there was no evidence of spills. One listing referenced health limit exceedences in water samples from the Copco Lake Municipal Water Company for radium-228, arsenic (total), bromodichloromethane, dichloroacetic acid, and total haloacetic acids between 2004 and 2006, and for aluminum in water samples collected since 2004. The remaining listing resulted from a minor spill which was remediated and is no longer a site of concern, as described below:

- **21630 Copco Road (Map Location #2 – 21630 Copco Road, Hornbrook, CA).** This site, which is the Copco 2 powerhouse, had a spill of non-polychlorinated biphenyl (PCB) transformer oil and is listed in the California Hazardous Material Incident Reporting System and the Emergency Response Notification System databases. According to the EDR report, in 1999, a bushing failed at a transformer adjacent to the Klamath River releasing transformer oil. Most of the non-PCB transformer oil was contained, and less than 1 quart made it to the Klamath River. According to PacifiCorp, Siskiyou County conducted the site review and approval of the transformer fire spill cleanup (EDR 2010a).

In addition to the four sites described above, the EDR database research identified 162 “orphan sites,” which are those sites that could not be mapped or “geocoded” due to inadequate address information, along the two corridors of the Klamath River. After further research, seven orphan sites were identified within the area of analysis. Two of these seven were listings of National Pollutant Discharge Elimination System-permitted facilities and a Waste Discharge System facility, which do not present concerns related to HTRW. Another two of the listings indicated the presence of both aboveground and underground storage tanks at Iron Gate Salmon & Steelhead Hatchery and the J.C. Boyle Power Plant, in addition to the Copco 2 tank discussed above. There is no database-documented evidence of spills at Iron Gate or J.C Boyle. One site, listed on the Emergency Response Notification System, is the Copco 2 powerhouse minor spill described above. The remaining two sites were listed on the California Facility and Manifest Database and the leaking underground storage tank (LUST) databases. No

additional information was available on the Regional Water Quality Control Board Geotracker database or the California Department of Toxic Substances Control Envirostor database regarding these sites:

- **DFG Iron Gate Fish Hatchery (Hornbrook, CA).** This site is listed in the California EnviroStor Database (DTSC 2012). No additional information on the presence of HTRW at the site is available.
- **Weyerhaeuser Co., Klamath Mill Site (Highway 66 West, Klamath Falls, OR).** This site is listed in the underground storage tank (UST) and Geotracker databases (SWRCB 2012). No additional information on the presence of HTRW at the site is available.

In addition to the EDR database search, the following items were found from other sources:

- In 2009, at the Copco 1 Warehouse, soil known to be contaminated by petroleum products was removed from a former lube rack area. The final report and site cleanup were approved by a letter from Siskiyou County in 2010 (personal communication with R. Dean, Siskiyou County, March 30, 2011).
- In 2009, a former landfill site at Copco 2 Dam was removed per Siskiyou County review and approval (personal communication with R. Dean, Siskiyou County, March 30, 2011).
- Copco 2 Dam's fueling facility has two aboveground storage tanks (1,000-gallon gasoline and 500-gallon diesel). No known spills or cleanups occurred at this facility.

3.21.3.2 HTRW at PacifiCorp Dams and Associated Facilities

The existing dams and hydroelectric facilities have components that contain potentially hazardous materials. This analysis assumes that all painted structures, equipment, and metalwork in the project area contain heavy metals, such as lead. Window caulking, electrical wiring and components, building materials, and some coatings may contain asbestos. Tests for lead paint and asbestos are usually performed to characterize material and equipment prior to equipment removal and structure demolition. While PacifiCorp has tested their facilities for lead paint and asbestos in the past, the Lead Agencies have not verified the presence or absence of these materials as part of the development of this EIS/EIR or the Detailed Plan. In addition, surrounding soils may contain heavy metal contaminants where coatings have flaked off of the painted structures, equipment, and metalwork.

In the mid-1980s, PacifiCorp tested all of its accessible oil-filled electrical equipment for the presence of PCB materials (personal communication with T. Hepler, Reclamation, December 23, 2010.). All accessible power generation equipment was certified by PacifiCorp as "PCBs-free", if it had concentrations of PCBs that were less than 50 parts per million. Certain closed systems, such as transformer bushings, cannot be tested until time of disposal. Thus, small quantities of PCBs may be present in hydraulic fluids,

soils, and in older fluorescent light fixtures. Old light switches may contain mercury. Other hazardous materials at the dams and hydroelectric facilities may include transformers, batteries, bushings, oil storage tanks, bearing and hydraulic control system oils, lead bearings, and creosote-treated wood in the wood-stave penstocks.

It is unlikely that the dams themselves include naturally hazardous materials such as fibrous chrysotile asbestos that is a common mineral component found in serpentine rock. Serpentine is a rather weak metamorphic rock that would not typically be used in the manufacture of concrete which is what makes up the Copco dams. J.C. Boyle and Iron Gate dams are earthfill dams that are underlain by relatively young volcanic rocks of the Cascade Range geomorphic province. It is assumed that the earthen fill of those dams was derived locally from quarries excavated into the volcanic rock. The closest exposures of ultramafic rocks (i.e., serpentinized rocks) with reported occurrences of asbestos (Van Gosen and Clinkenbeard, 2011) lie approximately 18 miles due west of Iron Gate dam in the Round Mountain vicinity of the Klamath Mountains geomorphic province. Due to the distance and the relative weakness of serpentine rock compared to young volcanic rock in an engineered fill, it is unlikely that serpentine rock from the Round Mountain area was used in the construction of the dams. However, based on the age of the structures at Iron Gate and J.C. Boyle dams the concrete in the structures may contain fly ash, which has raised concerns about the presence of mercury or other toxic substances. However, the United States Environmental Protection Agency (USEPA) recognizes the beneficial uses of fly ash and considers it safe when it is encapsulated in concrete or other building materials (USEPA 2011). There is also a potential for changes to pH in river water during demolition of concrete.

As part of the Secretarial Determination studies, reservoir sediment cores were analyzed for a suite of inorganic and organic contaminants to assess the potential environmental and human health impacts of sediment release. Sediment contaminant levels in samples from the Klamath River were collected at multiple sites and at various sediment depths per site in J.C. Boyle Reservoir, Copco Reservoir, Iron Gate Reservoir, and the Klamath River Estuary, for a total of 77 samples (Department of the Interior (DOI) 2010). The sediment evaluation process followed screening protocols of the Sediment Evaluation Framework (SEF)¹ for the Pacific Northwest, issued in 2009 by the interagency Regional SEF Team.

The SEF sediment chemistry screening process indicated that the sediment deposits in the Klamath River reservoirs are not highly contaminated. There are few positive exceedances of relevant screening values, and therefore little positive indication that substantial aquatic toxicity, or ecological or human health risk, would likely result from exposure to the sediments. Results from elutriate and sediment toxicity bioassays and sediment bioaccumulation tests carried out for the Secretarial Determination studies are used to provide additional information beyond simple comparisons of sediment contaminant levels to individual-contaminant regional or national screening levels. The

¹ The SEF is a regional guidance document that provides a framework for the assessment and characterization of freshwater and marine sediments in Idaho, Oregon, and Washington (Regional Sediment Evaluation Team 2009).

results of sediment and elutriate toxicity bioassays provide a direct assessment of potential toxicity that takes into account possible interactive effects of mixtures of multiple contaminants, and of potential contaminants that may be present but were not individually measured. Each of these biological testing approaches have been conducted on the same reservoir sediment samples evaluated in the chemistry screening described above. The results of the study are presented in Section 3.2. See Section 3.2.4.3.1.7 and Appendix C.

3.21.3.3 School Sites in the Project Area

As shown in Figure 3.21-1, the closest existing schools to the area of analysis are Hornbrook Elementary School, Willow Creek Elementary School, Bogus Elementary School, and Keno Elementary. All four of these schools are located more than a mile away from the dam facilities. Keno Elementary is 0.25 miles from the Keno Impoundment at its nearest point.

3.21.3.4 Hazardous Waste Disposal Facilities

Any hazardous waste generated from the demolition of the dams and associated hydroelectric facilities would need to be disposed of in designated hazardous waste landfills. This would include treated wood waste, PCBs present in transformers and other electrical equipment, asbestos-containing materials in building materials, fuels and oils, concrete dust (if it generates high pH waste) and soils or other material contaminated with lead from the use of lead-based paint.

The Anderson Landfill in Anderson, California, located 122 miles from Hornbrook, California, is permitted to accept hazardous waste, including treated wood waste. The Anderson Landfill had an estimated remaining capacity of 4,925,975 cubic yards (70 percent of capacity remaining) in 2000, with an anticipated closure date of 2055.

3.21.4 Environmental Consequences

3.21.4.1 Effects Determination Methods

To evaluate whether the construction/demolition areas contain existing hazardous materials, EDR conducted a search of regulatory databases to identify facilities within the vicinity of the dams where hazardous materials are known to be present based on regulatory records of investigation and/or remediation conducted under the oversight of Federal, State, or local agencies. The area of analysis was divided into three corridors along the Klamath River within Oregon and California (EDR 2010a, 2010b, and 2011). The first corridor starts where Keno Impoundment/Lake Ewauna meet in Oregon and follows approximately 18 miles of the Klamath River within south central Oregon to the Keno Dam in Keno, Oregon. The second corridor includes the northeastern point of the J.C. Boyle Reservoir to the J.C. Boyle Powerhouse, and covers approximately 8 miles of the Klamath River within south central Oregon. The third corridor includes the northeastern point of the Copco 1 Reservoir, Copco 1 Dam, Copco 2 Dam, Iron Gate Reservoir, and Iron Gate Dam, and covers approximately 12.5 miles of the Klamath

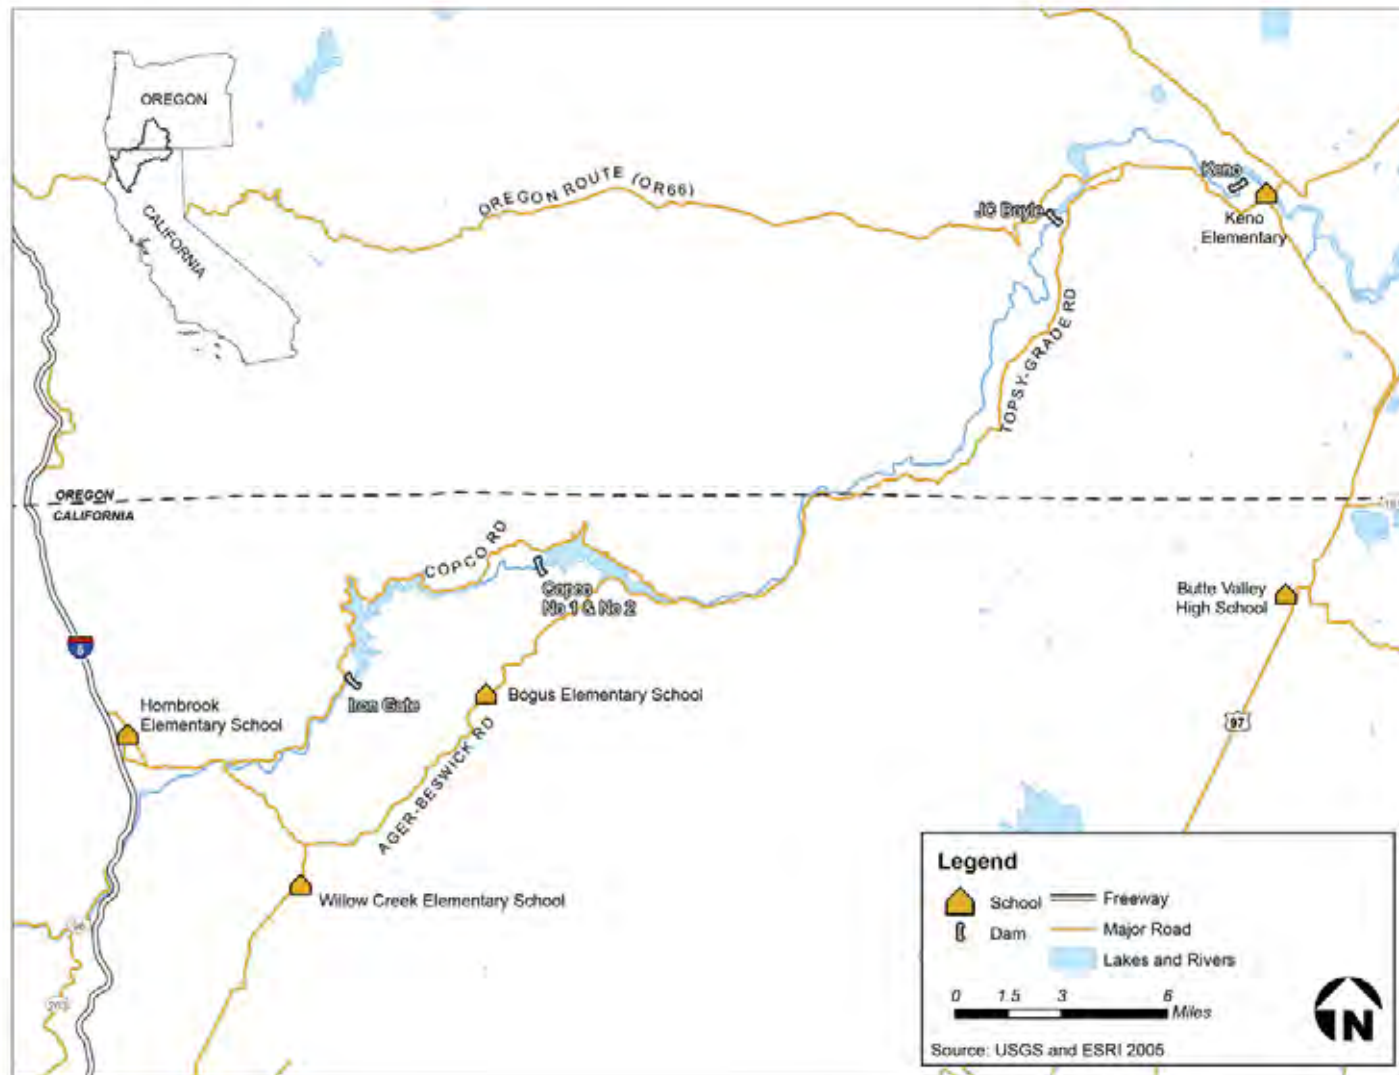

Figure 3.21-1. School Sites in the Project Area.

River within northern California. A 2-mile buffer was added for the records research to account for ground water migration and contaminant transport and to account for the width of the reservoirs. Figures 3.21-2, 3.21-3, and 3.21-4 show the area searched and an overview of the identified HTRW sites.

Database information on these sites was augmented by searching online databases of regulatory agencies to verify the closure status of sites or obtain information on the type and extent of contamination at the sites. Information on hazardous materials associated with existing dam components was obtained from PacifiCorp.

Although the databases search by EDR are updated regularly, there may be contaminated sites that have not yet been identified and are absent from the databases. A complete Phase I Environmental Site Assessment was not performed because such investigations tend to remain valid for only 6 months and, as a result, are typically done closer to the time of construction.

3.21.4.2 Significance Criteria

For the purposes of this Environmental Impact Statement/Environmental Impact Report (EIS/EIR), impacts related to HTRW would be significant if an alternative would result in any of the following:

- Creation of a significant hazard to the public or the environment through the transport, use, or disposal of hazardous materials;
- Creation of a significant hazard to the public or the environment through reasonably foreseeable accident conditions involving the release of hazardous materials into the environment;
- Generate hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school; or
- Be located on a site which is included on a list of hazardous materials sites and, as a result, create a significant hazard to the public or the environment.

3.21.4.3 Effects Determinations

The following sections contain descriptions of the hazardous waste effects that would occur under each alternative.

There are no schools located within one quarter mile of construction areas; the nearest schools are located more than 3 miles away. Therefore, there would be no impacts related to emissions or handling hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school. For this reason, the third significance criterion listed above does not apply to any of the alternatives and will not be considered further in this analysis.

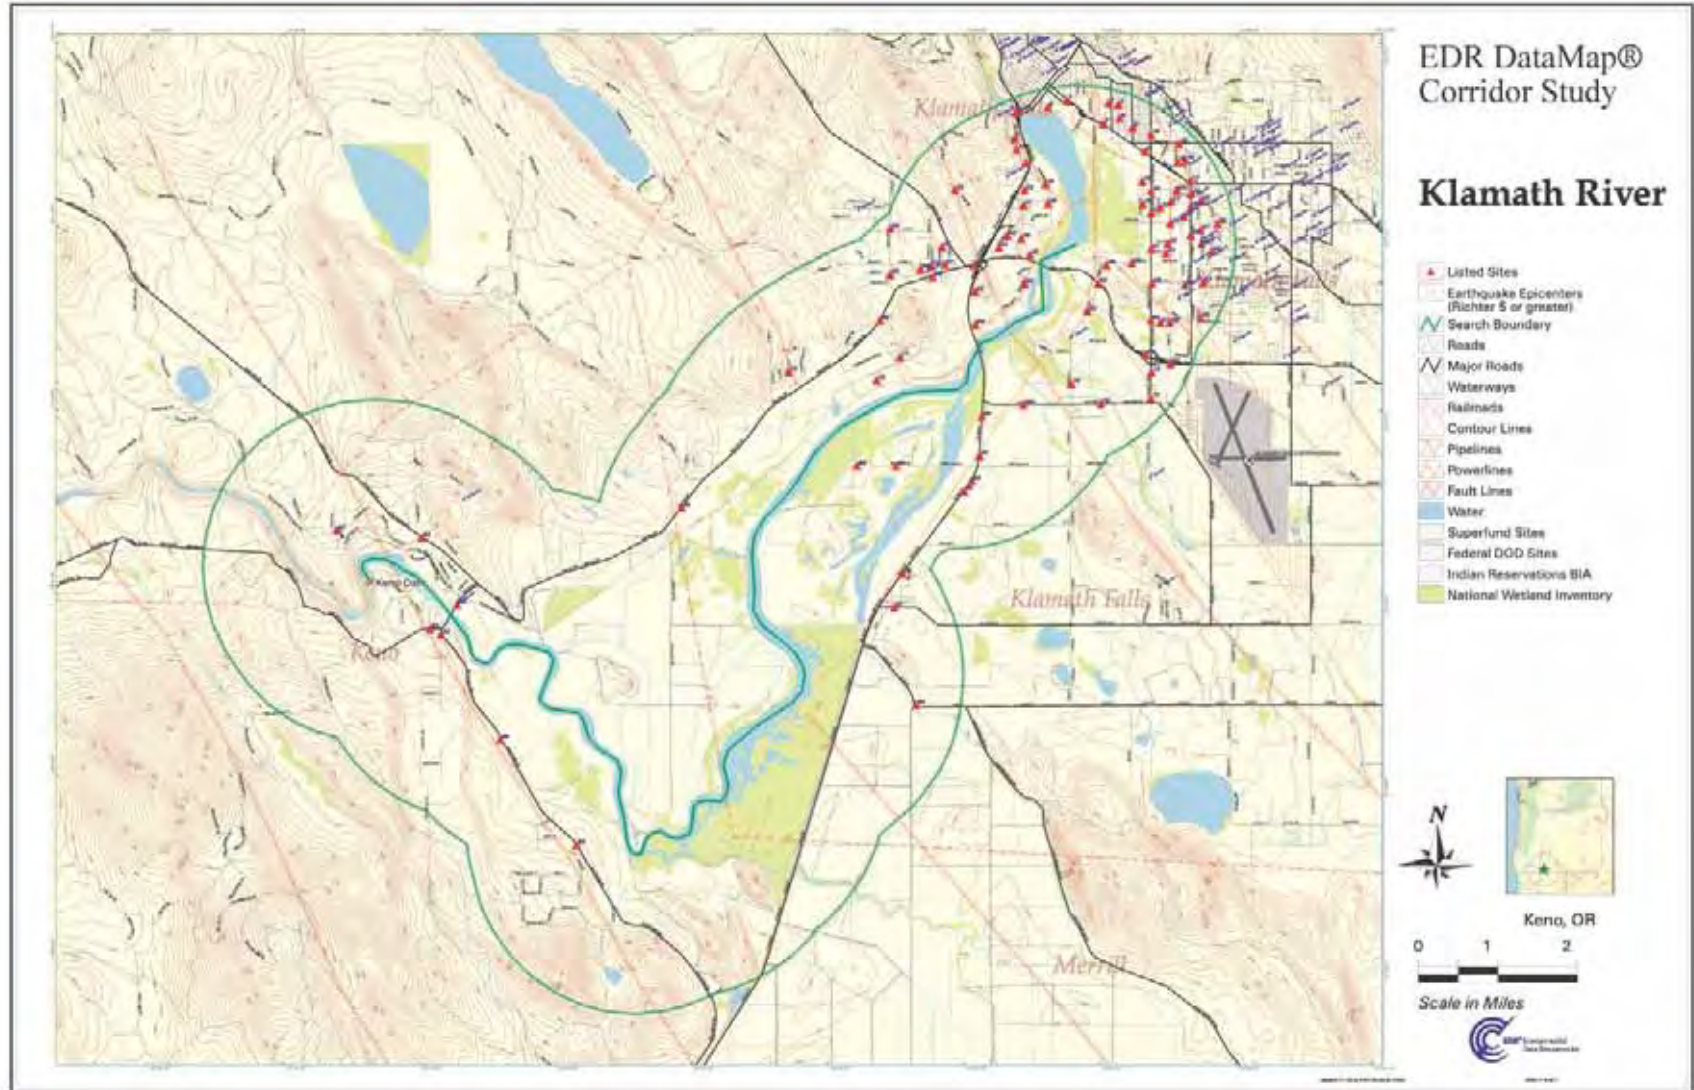

Figure 3.21-2. HTRW Sites, Keno Dam and Keno Impoundment/Lake Ewauna.

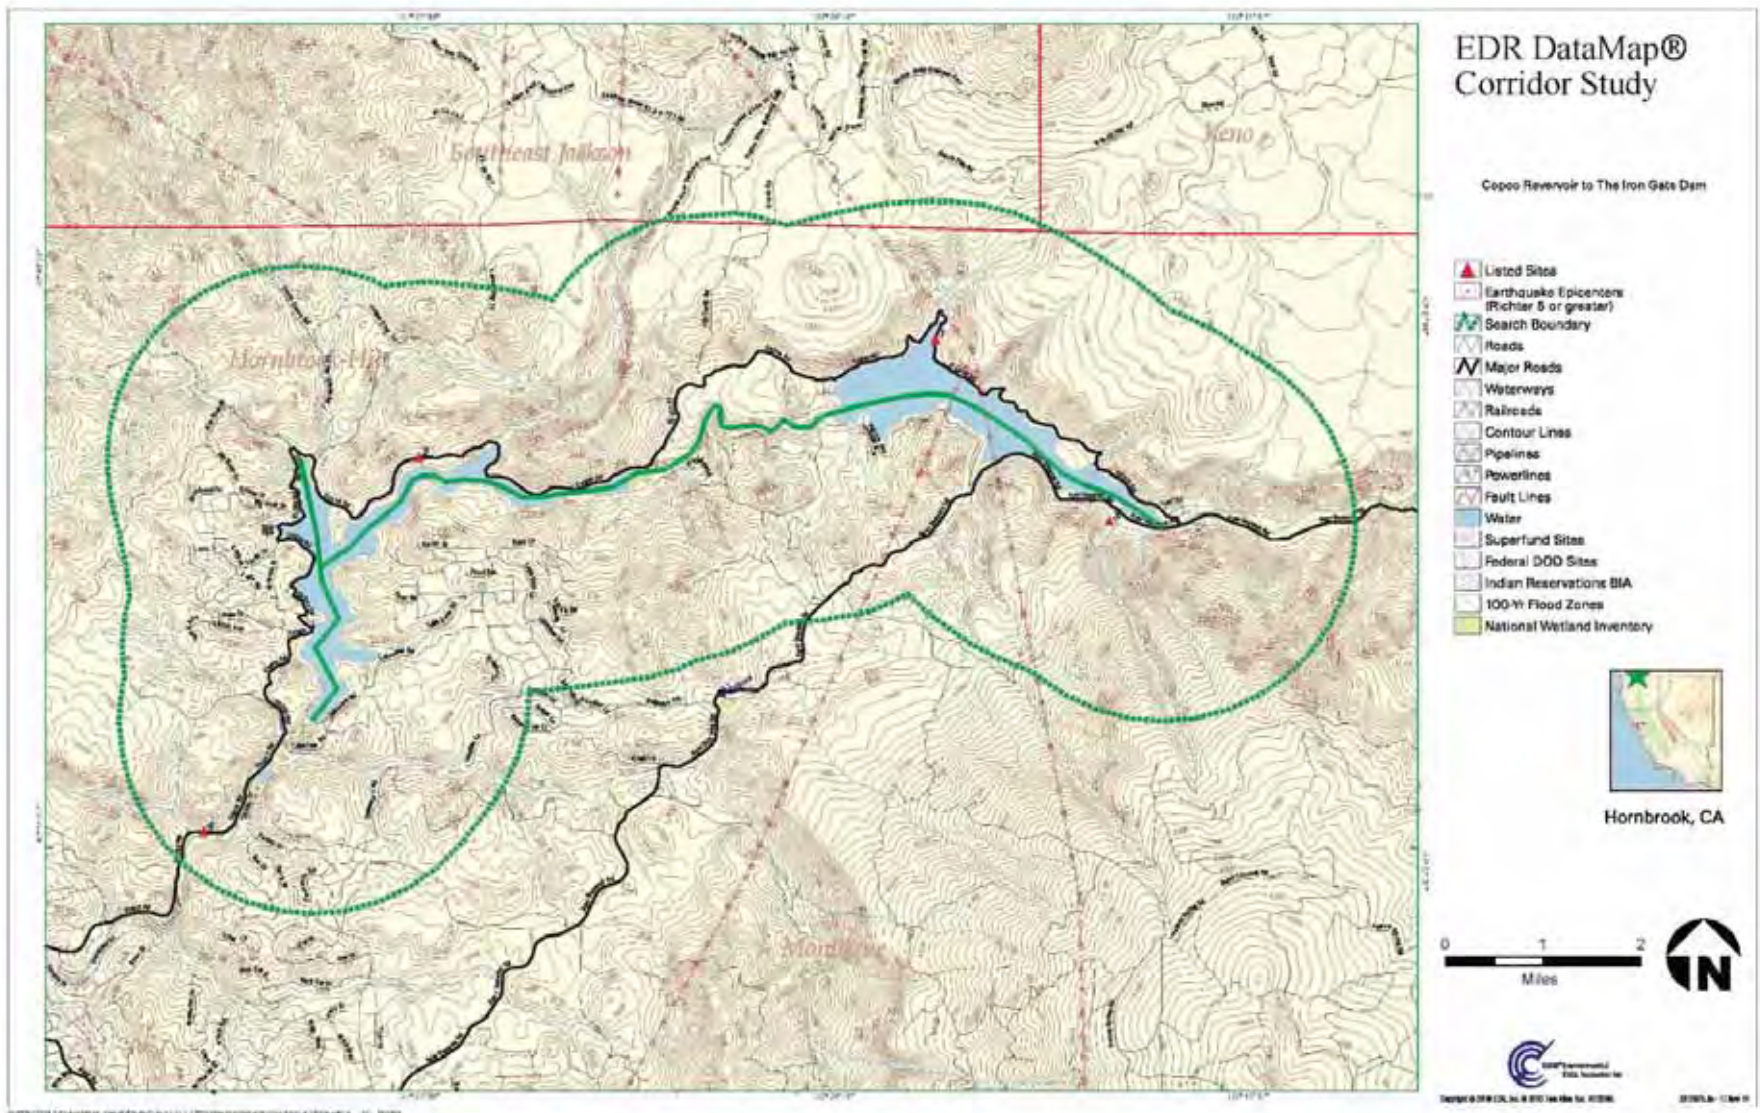

Figure 3.21-3. HTRW Sites, Iron Gate and Copco Dams and Reservoirs.

Figure 3.21-4. HTRW Sites, J.C. Boyle Dam and Reservoir.

To assess hazardous waste effects that could occur under each alternative, the analysis focused on potential hazards that could be encountered during deconstruction of the dam facilities, construction of fish passageways, and resultant restoration of the deconstruction/construction areas. The potential resulting risk to the public from these activities are described qualitatively. To identify potential hazards to the public from the alternatives, the inventory of existing hazardous materials at the dams and associated facilities was reviewed to assess potential risks associated with their deconstruction and removal. In addition, the EDR database search was used to identify known hazardous material sites within the area of analysis that could be disturbed during deconstruction/construction activities.

According to the information provided in the EDR search, construction areas for the Proposed Action and the other action alternatives are not located near sites where hazardous materials are known to occur. Since the EDR report identified a very small number of sites of concern located within one mile of the construction areas, the potential for hazards related to encountering contaminated soil or ground water from these sites is low, however, this risk is discussed below.

3.21.4.3.1 Alternative 1: No Action/No Project

The No Action/No Project Alternative could create a hazard to the public or the environment through the handling, transport and disposal of HTRW. Under the No Action/No Project Alternative, no new construction or demolition would occur at the four Klamath dams so existing known hazardous sites would not be disturbed and would not pose a threat to public safety. Hazardous components of the existing dams, such as transformers, bushings, tanks, lead bearings, creosote-wood staves, and asbestos-based insulating products, would not be disturbed. Any hazardous waste generated or used during operation of the existing dams and hydroelectric facilities and during construction of the Ongoing Restoration Actions (e.g., at Wood River, Barnes, etc.) would be the same as under existing conditions. **Therefore, there would be no change from existing conditions related to HTRW under the No Action/No Project Alternative.**

3.21.4.3.2 Alternative 2: Full Facilities Removal of Four Dams (the Proposed Action)

The Proposed Action involves removal of all appurtenant features, with the exception of buried features, at the Four Facilities.

Facility deconstruction could occur on sites included on a list of hazardous materials sites and, as a result, create a significant hazard to the public or the environment. As summarized in Section 3.21.3.1, the EDR database search identified two listed hazardous sites within one mile of the area of analysis. One site involved a spill of non-PCB transformer oil on Copco Road in 1999, but less than one quart reached the Klamath River. Siskiyou County conducted the site review and approval of the transformer fire spill cleanup. The other reported site was the Copco Lake Municipal Water Company reporting health limit exceedances of radium-228, arsenic (total), bromodichloromethane, dichloroacetic acid, and total haloacetic acids in 2004 and 2006 and detections of aluminum exceeding both the health and legal limits since 2004. Due to the distance of

these two sites from the Four Facilities and construction areas, there is no potential to encounter HTRW from these two sites during construction and demolition activities under the Full Facilities removal of Four Dams alternative. . The EDR database search did not identify any other reported spills within the area of analysis; however, the databases searched by EDR are constantly being updated and require reporting by others to be complete. As such, there is the possibility that an unknown (i.e., unreported and unlisted) contaminated site could be encountered. **There would be no change from existing conditions related to posing a hazardous chemical risk from materials currently at the dam sites.**

Facility deconstruction could create a significant hazard to the public or the environment through the transport, use, or disposal of HTRW during construction. Hydroelectric facilities operate using a variety of chemicals (e.g., lubricants, transformer oils, bearing oils, etc.) that would be removed under decommissioning. The presence of a UST at the J.C. Boyle Power Plant does not indicate a spill; however, care should be exercised when conducting work in these areas. As part of the decommissioning plan, prior to initiation of deconstruction or construction activities, the contractor will be required to prepare a Hazardous Material Management Plan (HMMP) for review by the Dam Removal Entity in case contaminated media are encountered. The purpose of this plan is to have an established plan of action if known or unknown hazardous materials (e.g., soil or ground water contamination, asbestos and hazardous coatings requiring abatement, high pH generated during demolition of concrete, etc.) are encountered during construction/deconstruction and to establish best management practices (BMPs) to reduce the potential for exposure to hazardous wastes. The HMMP will contain the following:

- Definition of a protocol for proper handling, transport, and disposal of hazardous materials (e.g., creosote-treated wood staves, high pH concrete particles) if they are encountered during construction or deconstruction.
- Definition of a protocol for proper emergency procedures and handling, transport, and disposal of hazardous materials if an accidental spill occurs during construction.
- Establishment of BMPs to reduce the potential for spills of HTRW. Typical BMPs to reduce the potential for spills may include, but are not limited to:
 - Having a spill prevention and control plan with a designated supervisor to oversee and enforce proper spill prevention measures;
 - Providing spill response and prevention education for employees and subcontractors;
 - Stocking appropriate clean-up materials onsite near material storage, unloading and use areas;
 - Designating hazardous waste storage areas away from storm drains or watercourses;
 - Minimizing production or generation of hazardous materials on-site or substituting chemicals used on-site (e.g., herbicides during restoration) with less hazardous chemicals;

- Designating areas for construction vehicle and equipment maintenance and fueling with appropriate control measures for runoff and runoff; and
- Arranging for regular hazardous waste removal to minimize onsite storage.

Hazardous materials at the dam settings could include creosote-treated wood staves, asbestos, batteries, transformers, bearing and hydraulic control system oils, oil storage tanks, mercury light switches, and PCBs. In addition, coatings containing heavy metals in the powerhouse and on the exterior surfaces of the steel penstock and air vent pipes, surge tanks, bulkhead gates, and generator gantry crane would require specialized abatement and disposal. The volumes of most of these materials requiring special disposal (e.g., asbestos insulation and lead-based paint) have not been estimated because they cannot be easily quantified before abatement activities have been conducted.

Removal of Copco 2 Dam would generate an estimated 725 tons of treated wood material (creosote wood staves) that would require transport and disposal (analysis of impacts to regional waste facility capacity is presented in Section 3.18, Public Health and Safety, Utilities and Public Services, Solid Waste, and Power). In addition, if it is determined that the Lakeview Bridge just downstream from Iron Gate Dam is not adequate to support construction traffic from the decommissioning activities and needs to be replaced, creosote-treated wood from the bridge would require transport and disposal. Because the Anderson Landfill has an estimated remaining capacity of 4,925,975 cubic yards, the regional landfills in the surrounding counties should be capable of handling the additional generated waste hazardous waste. Licensed contractors would be selected to transport any waste designated as hazardous. The contractors would be required to comply with all hazardous waste laws for transport and disposal of hazardous materials. **With implementation of the HMMP during construction, impacts from the transport, use, and disposal of HTRW from dam removal would be less than significant.**

Facility deconstruction could create a significant hazard to the public or the environment through the abatement and disposal of asbestos and lead-based paint during construction. In addition, as noted under existing conditions, paint coatings on the buildings and structures may have flaked off into the surrounding soil, creating localized areas of soil contamination that would need to be properly excavated and disposed of. However, as part of the decommissioning plan, the demolition contract will require evidence be provided to the responsible Federal agency prior to issuance of demolition permits that a qualified asbestos and lead-based paint removal contractor/specialist has been procured to remove or otherwise abate asbestos and lead-based paint prior to or during demolition activities in accordance with Federal, State, and local regulations. In addition, evidence will be provided to the responsible Federal agency that the demolition contract provides for construction contracts and/or land/building leases, provisions shall be included requiring continuous compliance with all applicable government regulations and conditions related to hazardous materials and waste management. **Therefore, impacts associated with abatement and disposal of asbestos and lead-based paint would be less than significant.**

Facility deconstruction could create a significant hazard to the public or the environment through the accidental release of hazardous materials into the environment during construction. Construction equipment would require the use of hazardous materials (e.g., diesel and gasoline fuels, hydraulic oil). Restoration activities under the Proposed Action would require trucks for hauling equipment and raw materials including spawning-size pea gravel, aircraft for applying hydromulch, discing equipment, backhoes, and other equipment. Restoration could also include the application of herbicides or pesticides. Fuels, oils, and other hazardous materials used during construction could be accidentally released within construction, staging, and access areas through spills, fueling, and equipment repair.

As part of the decommissioning plan, the contractor will be required to prepare and implement a worker Health and Safety Plan (HASP) prior to the start of construction activities. The HASP will, at a minimum, identify the following:

- All contaminants that could be encountered during excavation activities
- All appropriate worker, public health, and environmental protection equipment and procedures
- Proper housekeeping and BMP procedures to prevent spills or migration of herbicides/pesticides
- Emergency response procedures
- Most direct route to a hospital
- Site Safety Officer

The plan will require documentation that all workers have reviewed and signed the plan.

With implementation of the HMMP and the HASP during construction of the Proposed Action, impacts from the accidental introduction of hazardous materials would be less than significant.

Drawdown of the reservoirs would require removal of recreational facilities currently located on the banks of the existing reservoirs. The existing recreational facilities provide camping and boating access for recreational users of the reservoirs. Once the reservoirs are drawn down, these facilities will be removed. Construction equipment used for the removal would require the use of hazardous materials (e.g., diesel and gasoline fuels, hydraulic oil). Fuels, oils, and other hazardous materials used during removal could be accidentally released within construction, staging, and access areas through spills, fueling, and equipment repair. An HMMP and HASP would be prepared, as described above. **With implementation of the HMMP and the HASP during construction of the Proposed Action, impacts from the accidental introduction of hazardous materials during the removal of the recreational facilities would be less than significant.**

Keno Transfer

The transfer of the Keno Facility to DOI could result in affects to HTRW. The Keno Transfer would result in a transfer of ownership of the Keno facility to DOI. There

would be no changes in operations or land use of the Keno Facility with the Keno Transfer. In addition, the EDR search did not identify any sites of concern related to HTRW that would change ownership under the Keno Transfer. Due diligence would be required prior to the Keno Transfer to ensure that any hazardous or toxic wastes and materials present on the properties are identified and fully disclosed. Should any be discovered, proper management would be necessary for PacifiCorp or DOI to manage the materials. **Therefore, the implementation of the Keno Transfer would result in no change from existing conditions.**

East and Westside Facilities – Programmatic Measures

The decommissioning of the East and Westside Facilities could have adverse effects in terms of toxics and hazardous materials. Decommissioning of the East and Westside canals and hydropower facilities of the Link River Dam by PacifiCorp is a part of the Klamath Hydroelectric Settlement Agreement (KHSAs). Currently, PacificCorp diverts water at Link River Dam into the two canals. These diversions would cease with the decommissioning of the East and Westside facilities. Following decommissioning of the facilities there would be no change in outflow from Upper Klamath Lake or inflow into the Link River. Appropriate health and safety plans would be created to limit the potential of toxic releases during decommissioning. **Therefore, there would be less than significant effects from the decommissioning activities.**

City of Yreka Water Supply Pipeline Relocation – Programmatic Measures

Removal of Iron Gate Reservoir would require the relocation of the City of Yreka Water Supply Pipeline, which could create a significant hazard to the public or the environment through the accidental release of hazardous materials into the environment during construction. The existing water supply pipeline for City of Yreka passes under the Iron Gate Reservoir and would be relocated prior to the decommissioning of the reservoir to prevent damage from deconstruction activities or increased water velocities once the reservoir has been drawn down. The pipeline would either be suspended from a pipe bridge across the river near its current location, or rerouted along the underside of the Lakeview Bridge just downstream from Iron Gate Dam. Construction equipment used for the relocation would require the use of hazardous materials (e.g., diesel and gasoline fuels, hydraulic oil). Fuels, oils, and other hazardous materials used during construction could be accidentally released within construction, staging, and access areas through spills, fueling, and equipment repair. An HMMP and HASP would be prepared, as described above. **With implementation of the HMMP and the HASP during construction of the Proposed Action, impacts from the accidental introduction of hazardous materials during the pipeline relocation would be less than significant.**

KBRA – Programmatic Measures

The following KBRA programs would entail construction, and therefore could result in impacts related to HTRW:

- Phases I and II Fisheries Restoration Plans
- Fisheries Reintroduction and Management Plan
- Wood River Wetland Restoration Project

- On-Project Plan
- Water Use Retirement Program
- Fish Entrainment Reduction
- Power for Water Management Program
- Additional Water Conservation and Storage

Construction activities associated with the KBRA programs could create a hazard to the public or the environment through the transport, use, or disposal of hazardous materials encountered during construction. Exact locations and construction plans have not yet been determined for the KBRA construction activities. Impacts related to creating a hazard through routine transport, use, and disposal of hazardous materials would be comparable to those described above for the Proposed Action. The potential for encountering contamination during construction activities for KBRA programs and the extent and frequency of excavation, transport, and disposal are unknown. At the time of implementation of KBRA programs, the entity implementing a KBRA program would follow environmental compliance guidelines with regards to applicable toxic and hazardous material laws. These construction actions would not be in the same location or occur at the same time as the hydroelectric facility removal actions. As a result, KBRA construction actions would not contribute to the potential hazardous material effects of facility removal actions. **Therefore, impacts from hazardous materials encountered during construction for KBRA would be less than significant.**

Construction activities associated with the KBRA programs could create a significant hazard to the public or the environment through the accidental release of hazardous materials during construction activities. Construction could require the use of equipment that use hazardous materials (e.g., fuels and oils) and an accidental release of these hazardous materials could occur. BMPs described in the affected environment would reduce any likelihood of accidental release. As noted above, at the time of implementation of KBRA programs, the implementing entity would follow environmental compliance guidelines with regards to applicable toxic and hazardous material laws. These construction actions would not occur in the same place or at the same time as the hydroelectric facility removal actions. As a result, these actions would not contribute to the effects of facility removal actions. **With implementation of standard BMPs during construction for the KBRA, impacts from the accidental introduction of hazardous materials would be less than significant.**

3.21.4.3.3 Alternative 3: Partial Facilities Removal of Four Dams

The Partial Facilities Removal of Four Dams Alternative could create a significant hazard to the public or the environment through the transport, use, or disposal of hazardous materials encountered during construction or the accidental release of HTRW during construction. Under the Partial Facilities Removal of Four Dams Alternative, certain project features at the Four Facilities would be retained. Impacts related to HTRW for the Partial Facilities Removal of Four Dams Alternative would be the same as that associated with the Proposed Action. Table 2-22 in Chapter 2, Proposed Action and Description of the Alternatives, lists features that would be removed under the Proposed

Action, but would remain in the Partial Facilities Removal of Four Dams Alternative that could potentially reduce the amount of hazardous waste requiring abatement or disposal. Although all of the specifically identified powerhouse hazardous materials (transformers, batteries, and insulation) would be removed under both alternatives, some materials that contain hazardous coatings could be retained under the Partial Facilities Removal of Four Dams Alternative and would be stabilized through ongoing maintenance activities (e.g., painted penstocks that are left in place under this alternative would be recoated periodically as maintenance). **With implementation of the HMMP and the HASP during construction, impacts associated with the handling, transport, and disposal of hazardous materials and the accidental release of hazardous materials during construction of the Partial Facilities Removal of Four Dams Alternative would be less than significant.**

Keno Transfer

The effects of the Keno Transfer would be the same as those described for the Proposed Action.

East and Westside Facilities – Programmatic Measures

The effects of the East and Westside Facilities removal would be the same as those described for the Proposed Action.

City of Yreka Water Supply Pipeline Relocation – Programmatic Measures

The effects of the relocation of the City of Yreka Water Supply Pipeline would be the same as the Proposed Action.

KBRA – Programmatic Measures

The KBRA would be fully implemented under this alternative. Effects would be the same as the Proposed Action.

3.21.4.3.4 Alternative 4: Fish Passage at Four Dams

Under the Fish Passage at Four Dams Alternative, no facilities removal would be conducted. This alternative would include the construction of fish passageways at each of the Four Facilities. Known hazardous materials associated with the facility structures would remain in place and there would be no anticipated handling, transport, or disposal of HTRW.

The Fish Passage at Four Dams Alternative could create a significant hazard to the public or the environment through the accidental release of hazardous materials into the environment during construction. Construction would require the use of hazardous materials (e.g., fuels and oils) within construction areas. The scale of the construction would be much smaller for the construction of the Fish Passage at Four Dams Alternative than it would be under the Proposed Action and Partial Facilities Removal of Four Dams Alternatives. **With implementation of the HMMP and the HASP during construction, impacts from the accidental release of hazardous materials would be less than significant.**

3.21.4.3.5 Alternative 5: Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate

The Fish Passage at Two Dams Alternative could create a significant hazard to the public or the environment through the transport, use, or disposal of hazardous materials encountered during construction or the accidental release of HRTW during construction. Under the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative, the Dam Removal Entity would remove the facilities at Copco 1 and Iron Gate Dams. Fish passage facilities would be constructed at J.C. Boyle and Copco 2 Dams. Impacts related to hazardous materials for the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative would be the same as for the Proposed Action at the Copco 1 and Iron Gate Dams, and would be the same as for the Fish Passage at Four Dams Alternative at J.C. Boyle and Copco 2 Dams. **With implementation of the HMMP and the HASP during construction, impacts associated with the handling, transport, and disposal of hazardous materials and the accidental release of hazardous materials would be less than significant.**

City of Yreka Water Supply Pipeline Relocation – Programmatic Measures

The effects of the relocation of the City of Yreka Water Supply Pipeline would be the same as the Proposed Action.

3.21.4.4 Mitigation Measures

3.21.4.4.1 Mitigation Measure by Consequence Summary

Impacts associated with hazardous materials under each of the alternatives would be less than significant with the implementation of the HMMP and HASP; therefore, no mitigation measures would be required.

3.21.4.4.2 Mitigation Measures Associated with Other Resource Areas

Construction of new recreation facilities could release hazardous materials. Mitigation measure REC-1 would create a plan to develop recreational facilities and access points along the newly formed river channel between J.C. Boyle Reservoir and Iron Gate Dam. Recreation facilities, such as campgrounds and boat ramps, currently located on the edge of the reservoir would need to be replaced in appropriate areas near the new river channel once the reservoir is removed. Construction equipment used for the new construction would require the use of hazardous materials (e.g., diesel and gasoline fuels, hydraulic oil). Fuels, oils, and other hazardous materials used during construction could be accidentally released within construction, staging, and access areas through spills, fueling, and equipment repair. An HMMP and HASP would be prepared, as described above. **With implementation of the HMMP and the HASP, impacts from the accidental release of hazardous materials during construction of new recreation facilities would be less than significant.**

3.22 Traffic and Transportation

This section describes how the Proposed Action and alternatives could affect the area's transportation and circulation. This section includes a description of the area of analysis, the local and direct access routes identified to be used during construction, the existing non-motorized transportation network, and transit resources. This section also contains an analysis of future traffic volumes resulting from each alternative and describes mitigation measures to reduce impacts during construction. Appendix S includes tables that support this transportation and circulation analysis, and Appendix T describes 2020 Traffic Volume Projections.

3.22.1 Area of Analysis

The area of analysis for the Klamath Hydroelectric Settlement Agreement (KHSA) includes roadways in Siskiyou and Shasta Counties in California and Klamath and Jackson Counties in Oregon. The area of analysis for the KHSA is rural with very low-density development. Most of the private property is undeveloped and/or used as grazing land for cattle with the exception of several small communities in the vicinity of Copco 1 and Iron Gate Reservoirs. Figure 3.22-1 depicts the transportation network in the area of analysis for the KHSA. The area of analysis for the Klamath Basin Restoration Agreement (KBRA) constitutes the entirety of the Klamath Basin and can be characterized as both urban and agricultural.

Table 3.22-1 lists the dam sites within the KHSA along with the corresponding regional and local roads that access each site.

3.22.2 Regulatory Framework

This analysis uses Oregon Department of Transportation (ODOT) and California Department of Transportation (Caltrans) accepted methods for measuring impacts on roadways. The Lead Agencies used these guidelines in the absence of county level guidelines. Caltrans measures traffic capacities in terms of a Level of Service (LOS). In California, the Siskiyou County General Plan is used as a guide in determining significance (1988). The ODOT system of congestion measurement is different from the LOS system that Siskiyou County and Caltrans use. The ODOT, Klamath County, and Jackson County, use a volume-to-capacity (v/c) ratio.

Where roadway planning level capacities were desired, and were not available from ODOT, Caltrans or County sources, the Lead Agencies used Caltrans accepted guidelines developed by the Florida Department of Transportation (FDOT) to outline roadway planning capacities in the project area.

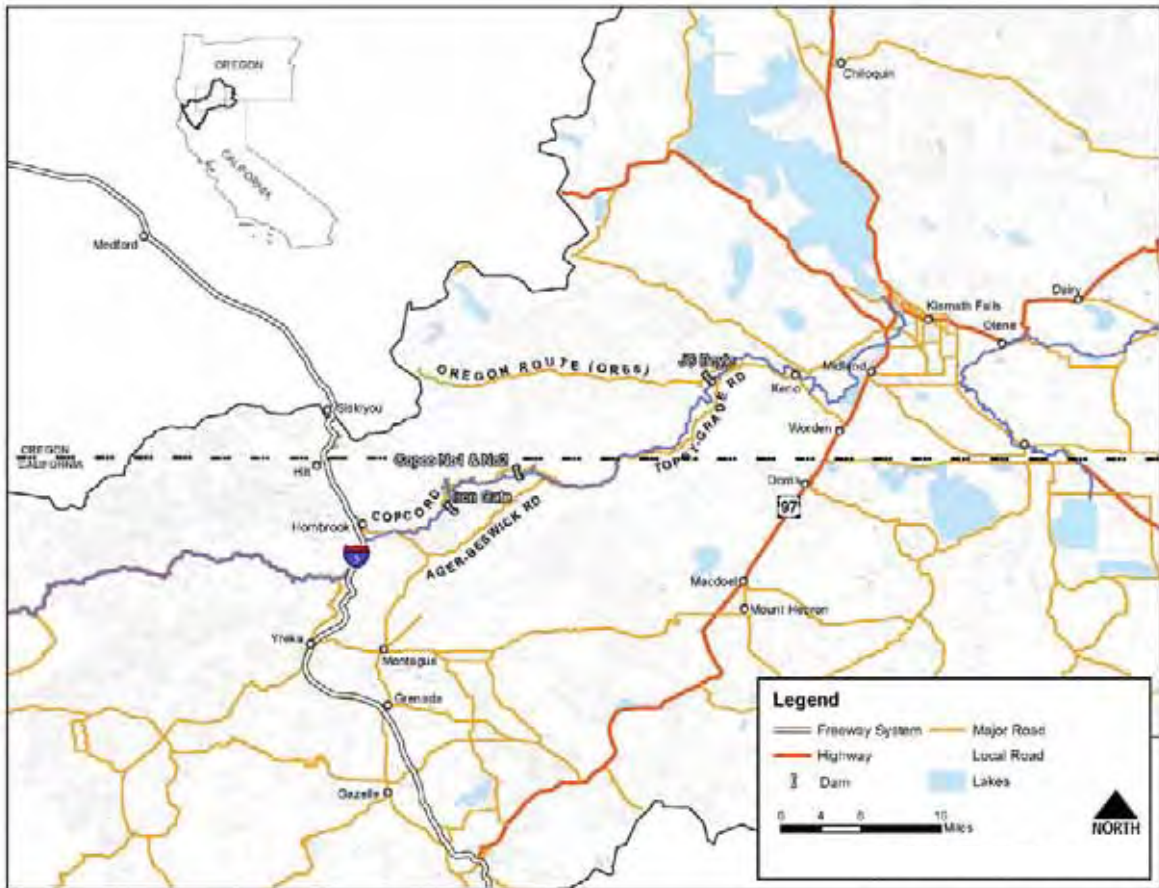

Figure 3.22-1. Regional Access Routes Relative to the KHS.

Table 3.22-1. Local and Regional Access Roads Relative to KHS

Dam Site	Interstate Access Road	Regional Access Road	Local Access Road
J.C. Boyle	Interstate 5 (1-5) (in Oregon) and US97	Oregon Route (OR) 66	Topsy Grade Road
Copco 1	I-5 (in California)	Copco Road	Ager-Beswick Road
Copco 2	I-5 (in California)	Copco Road	Ager-Beswick Road
Iron Gate	I-5 (in California)	Copco Road	Lakeview Road

Source: CDM field observation, Oct 2010.

3.22.2.1 Significance Criteria

For the purposes of the Klamath Facilities Removal Environmental Impact Statement/ Environmental Impact Report (EIS/EIR), effects would be significant if they resulted in one or more of the following conditions or situations:

- An alternative conflicted with an applicable plan, ordinance, or policy establishing measures of effectiveness for the performance of the circulation system.¹ (Traffic Flow Effects)
- Non-compliance with county planning regulations. (Traffic Flow Effects)
- Traffic related to implementation of the alternative resulted in a LOS worse than level C in Siskiyou County.² (Traffic Flow Effects)
- Traffic related to implementation of the alternative resulted in a v/c ratio of more than 0.75 for OR66 or 0.70 for U.S. Route 97 (US97).³ (Traffic Flow Effects)
- Traffic related to implementation of the alternative traversed blind corners or sharp turns; if large trucks would be turning onto and off of roadways with high speed limits; and/or if conflicts would occur at existing recreation sites where passenger cars may consistently turn in and out. (Traffic Safety Effects)
- An alternative conflicted with adopted policies, plans, or programs regarding public transit. (Public Transit Effects)
- Project-related vehicle volumes were great enough to exceed the capacity of a road in the area of analysis. This would slow or impede general vehicle traffic along a roadway and delay public transit service. Effects would also be significant if construction activities were adjacent to public transit passenger pick up/drop off facilities and inhibited vehicle travel or transit vehicle turning movements. (Traffic Flow Effects)
- An alternative resulted in the following Non-Motorized Transportation Effects:
 - Substantial degradation of road conditions that interfered with non-motorized vehicle use.
 - Conflict with adopted policies, plans, or programs regarding bicycle or pedestrian facilities.
 - Deconstruction or construction traffic crossing or running along existing non-motorized transportation facilities.
 - A need for the narrowing or rerouting of non-motorized transportation infrastructure such as a bicycle lane or sidewalk.

¹ Taking into account all modes of transportation including mass transit and non-motorized travel and relevant components of the circulation system, including but not limited to intersections, streets, highways and freeways, pedestrian and bicycle paths, and mass transit.

² In California, progressively worsening traffic conditions are given the letter grades “A” through “F.” While most motorists consider an “A,” “B,” or “C” LOS as satisfactory, LOS “D” is considered marginally acceptable. Congestion and delay are considered unacceptable to most motorists; these conditions would result in LOS “E” or “F” ratings. LOS analyses can be very detailed but for the purposes of this analysis LOS will only be discussed when referring to industry-accepted general planning standards for roadway capacity. LOS C is the threshold for capacity for California roads in this analysis. According to the Siskiyou County General Plan, LOS worse than level C is not acceptable (Siskiyou County 1988).

³ In Oregon, several different thresholds apply to various roads. A v/c ratio of 1.0 is equivalent to a poor LOS (E or F) with long delays. Klamath and Jackson Counties and ODOT are willing to accept a certain amount of congestion during peak periods to encourage drivers to find other modes of transportation or other times to travel. Jackson County requires that I-5 have a v/c ratio no higher than 0.85 (Jackson County 2005). Klamath County requires that OR66 have a v/c ratio no greater than 0.75 and US97 have a v/c ratio of no greater than 0.70 (Klamath County 2004).

3.22.3 Existing Conditions/Affected Environment

3.22.3.1 KHSA – River Reach Road Network

The following describes the characteristics of the roadways within the KHSA transportation analysis area. The Lead Agencies recorded these characteristics during site visits and relied on existing traffic volume data for the subject roadways from ODOT and Caltrans.

- **I-5** – a major north/south interstate highway that runs the length of California and continues through Oregon. This is a main regional access road for the Four Facilities on the Klamath River. Through Siskiyou and Jackson Counties, I-5 has four lanes. The posted speed limit is 70 miles per hour (mph) in California and 65 mph in Oregon. The portion of I-5 in California closest to the Iron Gate Dam has more than 17,000 vehicles per day in Annual Average Daily Traffic (AADT) in its peak month, and averages 15,200 AADT. In Oregon, near the intersection with OR66, traffic volumes are closer to 14,300 AADT.
- **OR66** – Known locally as Green Springs Highway, this road also carries the ODOT designation of Highway Number 21. OR66 is a two lane, east/west, asphalt State highway. It is approximately 32 feet wide and the posted speed limit is 55 mph in some locations. Some sharp curves on OR66 require posted speed reductions. OR66 connects I-5 to the J.C. Boyle Dam and to US97 and intersects I-5 approximately 14 miles north of the California border. Traffic counts from 2009 along OR66 show 9,500 AADT just east of I-5 and 500 AADT closest to the J.C. Boyle Dam.
- **US97** – Known locally as the California-Dalles Highway, this road carries the ODOT designation of Highway Number 4 and is a four-lane, north/south, asphalt US highway. A barrier divides the northbound and southbound lanes and it has a wide shoulder. The posted speed limit is 65 mph and AADT in 2009 was 9,700 vehicles.
- **Copco Road** – a minor collector that leads from I-5 to the Iron Gate, Copco 1 and Copco 2 Dams. Copco Road is a paved, two-lane road in good pavement condition with few pavement cracks or ruts and is approximately 27 feet wide. Copco Road maintains this character from its intersection with I-5 east to a point about 10 miles from the Copco Developments near the Juniper Point Picnic Area. The section between the intersection of Copco Road with Ager Road and the Juniper Point Picnic Area, contains intermittent pavement surfacing that has not been as well maintained as the portions to the west of Ager Road. The final 3 miles, from Camp Creek Road near the Juniper Point Picnic Area to the Copco Dams, are gravel and narrow, and less than 18 feet wide in some locations. The posted speed limit on Copco Road from I-5 to the Juniper Point Picnic Area is generally 55 mph with a few sharp curves, especially in the portions that run along the Iron Gate Reservoir. AADT for this analysis is based on field observation. See Figure 3.22-2 for a photo of a portion of Copco Road.

Source: Camp Dresser & McKee (CDM) 2010

Figure 3.22-2. Copco Road (north of river, facing west).

- **Topsy Grade Road and Ager-Beswick Road** – The roads known as Topsy Grade Road in Oregon and Ager-Beswick Road in California run along the southern side of the Klamath River and connecting the Copco 1 Reservoir to the J.C. Boyle Dam. The road sections between those two locations the road are mostly unimproved with natural surfacing. While these road sections have several different surfacing and sizing characteristics along it, the relevant portion, Topsy Grade Road near the J.C. Boyle Dam, is partially gravel and partially paved. It provides access to the Topsy Grade Recreation Area from OR66. Topsy Grade Road would give access to OR66 from the J.C. Boyle construction site, and Ager-Beswick Road would provide haul access, via Patricia Avenue (with construction of a temporary access connection along the dam abutment), from Copco 1 to the City of Yreka, California.
- **Unpaved access roads** – each dam has a small network of one lane, gravel access roads leading from either Copco Road or OR66 to the dams themselves. These roads are no wider than 15 feet and are no longer than ½ mile. Most of the traffic along these roads consists of PacifiCorp’s technicians accessing the facilities and recreational users.
- **J.C. Boyle unpaved access roads** – While this road network shares the same characteristics of the other unpaved access roads, it has a small bridge linking the north and south sides of the dam. This is a key link and might play a role in construction activities. Figure 3.22-3 is a photo of this bridge.

Source: CDM 2010

Figure 3.22-3. Access Bridge at J.C. Boyle Dam.

- **Lakeview Road** – a local road that accesses the Iron Gate Dam itself. Lakeview Road intersects with Copco Road at the entrance to the Iron Gate Recreation Area. A one-lane bridge crosses the river (see Figure 3.22-4) at this intersection linking to Lakeview Road. Lakeview Road is a gravel road that leads up to the top of Iron Gate Dam. It is approximately 24 feet wide and has a steep embankment on the east side, without a guardrail. Lakeview Road connects to an unnamed bridge access road. The narrow, gravel access road leads onto the top of Iron Gate Dam. For the purposes of further analysis, Lakeview Road would be considered an unpaved access road except when discussing the bridge.

Source: CDM 2010

**Figure 3.22-4. Bridge Accessing Lakeview Road
(looking south).**

- **Baseline Transit Service** - The Siskiyou Transit and General Express is the only transit service in the KHSA area of analysis. It is a regional service that connects the downtowns of Dunsmuir, Weed, Mt. Shasta, Grenada, McCloud, the City of Yreka, Montague, Fort Jones, Greenview, Etna, Klamath River, Horse Creek, Hamburg, Seiad Valley and Happy Camp. Service is very limited, sometimes running only one or two times a week. One route branches into the area of analysis and currently runs twice a week: the Hornbrook route. The Hornbrook route follows I-5 north into Hornbrook, turns east on Copco Road and then turns south (well before reaching the Iron Gate Dam) at Ager Road heading towards Montague, California.

In addition, Greyhound bus service runs on US97 connecting Klamath Falls to other cities in the region and to nearby Amtrak stations (Siskiyou County 2008). As with the Siskiyou Transit and General Express, this service is limited and is along a major U.S. highway.

- **Non-motorized Transportation Network** – The area of analysis has very few or no sidewalks and no designated bicycle routes of any kind. Because various camp and recreational sites exist throughout the KHSA area of analysis, it should be expected that bicycle riders and pedestrian travel along the river reach road network will be limited in capacity.

Specific information about the haul routes needed for construction and deconstruction activities as well as potential right-of-way requirements is provided in the Detailed Plan for Facilities Removal which will be produced if there is a Secretarial Determination. There would be subsequent environmental analysis on this plan to analyze traffic and transportation impacts from the Proposed Action.

3.22.3.2 KBRA – Road Network

The Upper Klamath Basin road network exhibits many of the same characteristics of the local access roads and other routes described for the KHSA area of analysis. Activities to be implemented that would likely affect transportation include the Phase I and Phase II Fisheries Restoration Plans. KBRA activities might include decommissioning local access roads, upgrading and/or replacing culverts to improve fish passage, and using backhoes and dump trucks to reshape channels and deliver gravel to augment fish spawning. Exact locations of these activities are currently undefined.

3.22.4 Environmental Consequences

3.22.4.1 Environmental Effects Determination Methods

3.22.4.1.1 Traffic Flow Effects

The scope of this analysis includes all roads that would experience construction related traffic. Routes were identified between each construction site and anticipated disposal sites. The greatest traffic flow effects would be nearest to the construction sites and those portions of the road were used during this analysis to assess potential impacts.

The Lead Agencies considered two components of traffic growth in evaluating future year conditions. First, the team determined an annual background growth rate based on historical data from 2000 through 2009. The Lead Agencies used that data to create a trend line and project baseline traffic volume to 2020. See Appendix T for the graphs showing these projections. Second, the Lead Agencies collected construction data including the number of construction trucks, construction truck routes and timing, number of workers, and worker traffic routes and timing. Lead Agencies provided this data for the project alternatives and added to the network any increases in traffic expected from each of the alternatives.

In addition to construction trucks hauling materials, construction workers accessing the sites may affect traffic flows in the area. Using construction worker forecasts and the current traffic volumes along available access roads, Lead Agencies projected traffic increases from workers. To access Iron Gate, Copco 1 and Copco 2 Dams, workers must travel along I-5 to Copco Road or Ager-Beswick Road. The worker access trip counts were assigned to these two roads. The J.C. Boyle Dam has two different directions from which workers might originate. In consideration of the current traffic volume to the east and west of J.C. Boyle Dam along OR66, this analysis uses the percentages of AADT to indicate how many workers might originate their trips from the east or from the west. Based on this analysis, the Lead Agencies assume that 12 percent of workers traveling to J.C. Boyle Dam would come from the west, taking I-5 to OR66 and 88 percent would come from the east, taking US97 to OR66.

The Lead Agencies used Caltrans accepted guidelines developed by the FDOT, along with road characteristics, to outline roadway planning capacities in the project area. The FDOT publishes a concise LOS Planning Handbook (2009) with service volume tables correlated to different roadway types and geometries, based on the Highway Capacity Manual (HCM). The HCM contains vast technical data that is very specific to traffic engineering technical analysis. The FDOT LOS Planning Handbook takes the detailed technical data from the HCM and summarizes it into a user friendly format that is appropriate for planning level analyses, such as is the case with this assessment.

Because the project area is remote and not generally considered to have peak commute times, the Lead Agencies assumed that existing traffic would largely be uniform throughout various times of day.

3.22.4.1.2 Traffic Safety Effects

Based upon site visits and map analysis, combined with review of planned truck hauling routes, the Lead Agencies identified roads with potentially hazardous points along them. Safety hazards include blind corners or turnouts and sharp turns or areas where slow construction traffic might conflict with high roadway speed limits. The Lead Agencies also assessed potential visibility hazards due to dust.

3.22.4.1.3 Public Transit Effects

The Lead Agencies examined the local and regional deconstruction traffic routes for each alternative and compared them to existing local and regional transit service routes to determine potential conflicts. The analysis relates traffic volumes to transit service because any road segments with projected traffic volumes over their functional LOSs could have disruptions in transit service.

3.22.4.1.4 Non-Motorized Transportation Effects

The Lead Agencies identified existing bikeways within the area of analysis and categorized them by class (bike path, bike lane, or bike route). The team also compared bikeways to construction traffic routes and timing to determine potential effects on the mobility and safety of cyclists and pedestrians. The team also reviewed available local or county planning documents addressing bicycle planning in the area of analysis to evaluate potential effects on planned bikeways. Although the project area would be a low pedestrian traffic area, the analysis addressed potential areas of conflict between trucks and pedestrians as well.

3.22.4.1.5 Road Condition Effects

In order to adequately assess the structural integrity and load carrying capacity of each road's surfacing section, a detailed geotechnical analysis would need to be conducted; this is out of the scope of this analysis.

3.22.4.2 Effects Determinations

3.22.4.2.1 Alternative 1: No Action/No Project Alternative

Traffic Flow Effects

Changes in traffic volumes could affect traffic flow. Any increase in traffic flow associated with the No Action/No Project Alternative would not exceed the planned LOS or v/c ratios for any roads in the area of analysis. **There would be no change from existing conditions from traffic flow effects.**

Traffic Safety Effects

Implementation of the Interim Measures (IMs) could cause traffic safety effects associated with sharp turns along Copco Road and OR66. Implementation of several IMs, including IM 7 – J.C. Boyle Gravel Placement and Habitat Enhancement (for one year) and IM 8 – J.C. Boyle Bypass Barrier Removal could result in increased traffic from haul trucks and construction workers; however, any increases in traffic flow would be minor and would not contribute substantially to the number of vehicles on the road. **This fact combined with the installation of signage at sharp turns along OR66 and Copco Road would reduce traffic safety effects associated with implementation of the interim measures to less than significant.**

Road Condition Effects

Changes in the road conditions could occur. Roads in the area of analysis would not experience wear greater than that for which they were designed under the No Action/No

Project Alternative. Any minor traffic safety conflicts would be mitigated through best management practices. **There would be no change from existing conditions from road condition effects.**

Public Transit Effects

Changes in public transit could occur. Public transit service would experience no negative effects from the No Action/No Project Alternative. Any minor public transit effects would be mitigated through best management practices. **There would be no change from existing conditions from public transit effects.**

Non-motorized Transportation Effects

Changes in non-motorized transportation could occur. There are no anticipated negative effects on non-motorized transportation due to the No Action/No Project Alternative. Any non-motorized transportation effects would be mitigated through best management practices. **There would be no change from existing conditions from non-motorized transportation effects.**

Ongoing Restoration Actions

While the KBRA would not be fully implemented under the No Action/No Project Alternative, ongoing restoration actions from Fish Habitat Restoration could have traffic and transportation impacts during construction activities.

Construction activities associated with the continued implementation of ongoing restoration actions could cause temporary effects to traffic and transportation.

Construction activities including channel construction, floodplain rehabilitation, fish passage and facilities construction, and breaching levees would likely involve the use of heavy equipment and construction vehicles. **Construction activities that would occur for the ongoing restoration programs are anticipated to result in potentially significant impacts to traffic and transportation. Best management practices incorporated into the project would minimize any traffic impacts to less than significant.**

3.22.4.2.2 Alternative 2: Full Facilities Removal of Four Dams (Proposed Action) Traffic Flow Effects

Transportation of equipment and supplies associated with dam facility deconstruction activities could result in temporary traffic flow effects on I-5, OR66, US97, and access roads. No long-term or permanent traffic volume increases or long-term changes in traffic patterns are expected as a result of the Proposed Action, including any changes resulting from shifts in recreation use described in Section 3.20, Recreation. Therefore, any transportation impacts associated with the Proposed Action would be limited in duration to the proposed deconstruction or construction period. The deconstruction and reservoir restoration schedule for the Proposed Action extends 18-months starting in May 2019. Work completed in 2019 would include small scale construction staging activities and analysis of road and bridge condition and any repair work that might be

identified during this analysis. The peak deconstruction activity and associated traffic would be generated in 2020; therefore this analysis is focused on the year 2020 when the largest effects would be anticipated.

The traffic projections for 2020, based on data from 2000 through 2009, indicate a decrease in baseline traffic on I-5 in California and OR66. In light of the recent increases in the cost of fuel and other economic factors, the years 2007 to 2009 may be an anomaly. When that data was excluded, I-5 showed an increase, but OR66 still showed a small decrease in the 2020 projection compared to baseline. In each case, the combined total of the projected baseline traffic volumes and the traffic that would result from implementation of each of the alternatives would not exceed the significance criterion for I-5, OR66, or US97 for any of the alternatives.

Table 3.22-2 consolidates the roadway planning capacities and the anticipated traffic for each alternative, and contains projected LOSs and v/c ratios. Appendix S presents a detailed analysis of the hauling and worker trips for each alternative. Hauling trips include trips to a local recycling facility in Klamath Falls, Oregon and the City of Yreka, California as well as truck trips for additional deconstructed materials to disposal sites outside of the project boundaries. As Table 3.22-2 shows, none of the main roads in the area of analysis would experience volumes in excess of their planned LOS or v/c ratio due to traffic resulting from implementation of the Proposed Action or the other alternatives. **Traffic flow effects on I-5, OR66, US97, and access roads would be less than significant.**

Transportation of equipment and supplies associated with dam facility deconstruction activities could result in temporary traffic flow effects on on-site roads. The only routes of concern with respect to traffic effects are the on-site gravel roads at each dam. The short but frequent heavy vehicle trips anticipated as part of dam deconstruction and reservoir restoration (the Proposed Action could generate over 1,500 AADT at some locations) could cause traffic flow concerns. Signage and construction traffic management to reduce construction traffic generated impacts would be implemented. **Traffic flow effects on on-site roads would be less than significant.**

Construction activities associated with the demolition of recreation facilities could result in temporary traffic flow effects on I-5, OR66, US97, and access roads. The demolition of recreation facilities would take place following dam deconstruction activities. Truck trips associated with construction activities at recreation sites would occur after the peak traffic period calculated for dam deconstruction activities. **Therefore, traffic flow effects on I-5, OR66, US97, and access roads would be less than significant.**

Table 3.22-2. Traffic Flow Projections

Roads	Road Type	Planning Capacity			No Action/No Project			Full Facilities Removal of Four Dams (Proposed Action)		
		LOS	v/c Ratio	AADT	LOS	v/c Ratio	AADT	LOS	v/c Ratio	AADT
I-5 (California)	Limited Access Interstate Highway	C	--	49,900	A	--	18,350	A	--	18,597

Key:

v/c: volume-to-capacity ratio

AADT: Annual Average Daily Traffic

LOS: Level of Service

Traffic Safety Effects

Activities associated with the Proposed Action, would cause traffic safety effects at each deconstruction site, on Copco Road, Topsy Grade/Ager-Beswick Road, and on OR66. The Lead Agencies have identified three potential areas of concern within the area of analysis.

Haul truck movement on unpaved roads could cause traffic safety effects associated with dust along gravel roads. High trip volumes would create a substantial amount of dust in dry conditions on Copco Road, Lakeview Road, Topsy Grade/Ager-Beswick Road, and the roads leading to and surrounding each dam. Parts of these roads have gravel surfaces. The dust would create a substantial visibility hazard for vehicles on the deconstruction sites throughout the area. Installation of signage, dust abatement and proper construction traffic management that would be implemented as a part of the Proposed Action would reduce the severity of this effect. **Visibility hazards caused by traffic-related dust generation would be a less than significant impact.**

Transportation of materials to and from the dam sites could cause traffic safety effects associated with vehicle turnouts along Copco Road, Topsy Grade/Ager-Beswick Road and OR66. If Copco Road, Topsy Grade/Ager-Beswick Road, Iron Gate and Copco 1 Reservoir Recreation Sites are open,⁴ there would be substantial safety concerns regarding traffic at the entrance to each small recreation parking area; this includes the boat launch downstream from Iron Gate Dam. The access road for the J.C. Boyle Dam is immediately off of OR66, where the posted speed limit is 55 mph. This location, while providing a clear view of oncoming traffic, would have a safety conflict related to speed differentials between construction vehicle traffic and normal vehicular traffic. Construction vehicles could pose safety risks to passenger and other vehicles traveling on roads in the project area. Construction vehicles travel at slower speeds, require more acceleration and deceleration time, and slow or stop traffic to make turns. Left turns across oncoming traffic could pose safety risks if truck acceleration is slow and oncoming speed limits were high. The following locations could experience traffic safety hazards related to conflicts between construction vehicles and regular traffic:

- Three boat launches and three camp sites along Copco Road.
- The recreation area accessed from Topsy Grade Road.
- One boat launch (access to the Klamath River) downstream from Iron Gate Dam, immediately adjacent to the bridge.

The installation of construction signage on OR66 and Copco Road in accordance with the Manual of Uniform Traffic Control Devices would reduce all traffic conflicts and alert oncoming traffic to slow merging construction traffic. **Traffic conflicts at vehicle turnouts along Copco Road, Topsy Grade/Ager-Beswick Road, and OR66 would be a less than significant impact.**

⁴ With the removal of the facilities, reservoir recreation opportunities would no longer exist. It is possible that Copco and Topsy Grade Roads may be completely closed to non-project related traffic during deconstruction with the exception of provisions for local residential access.

*Vehicles associated with dam removal could cause traffic safety effects associated with sharp curves along Copco Road and OR66. Both OR66 and Copco Road have several sharp turns that could require large construction vehicles to travel at very slow speeds. Copco Road narrows along certain portions of the roadway, and has many winding turns, mirroring the shore of the lake. **The installation of signage at sharp turns along OR66 and Copco Road would reduce this impact to less than significant.***

*The removal of existing recreation facilities could result in traffic impacts along adjacent roadways. As described in Section 3.20, Recreation, some recreation facilities, such as campgrounds and boat ramps, currently located on the reservoir banks would need to be removed once the reservoir is drained. These construction activities would occur at different times than dam removal deconstruction activities; thus, there would be no overlap in traffic volumes associated with deconstruction of the dams. **This fact combined with the installation of signage at sharp turns along OR66 and Copco Road would reduce traffic safety effects to less than significant.***

Road Condition Effects

Existing roads and bridge structures near the dam sites may not have adequate strength capacity for construction vehicles. Under the Proposed Action, further analysis of road conditions and bridge weight capacities would be necessary. Roads in the area of analysis do not have heavy traffic volumes and some do not have traffic from heavy vehicles, such as construction trucks. Some of the roads in the area of analysis may not have been designed to sustain heavy loads.

Three existing bridges in the area of analysis might be important for deconstruction efforts, but could be incapable of supporting and withstanding the weight of heavy deconstruction and hauling vehicles. Initial analysis of these bridges by the Lead Agencies indicated the potential need for repair or replacement prior to dam removal. Siskiyou County's schedule for maintenance of these facilities is unknown. Bridges include:

- A bridge at Iron Gate Dam connecting Copco Road to Lakeview Road. This is the only route that provides access to the south side and top of Iron Gate Dam.
- A bridge at J.C. Boyle Dam that provides access to the south side and top of that dam from OR66. At this location, an alternate route via Topsy Grade Road would allow construction vehicles to access the dam and avoid the bridge.
- Daggett Road Bridge used to access the Copco 2 Powerhouse.
- Jenny Creek Bridge was constructed on accumulated sediment. Preliminary engineering assessments identified the potential for movement of sediment during reservoir draw down that could deem the bridge structurally unsound. Replacement of the bridge at an alternate location would be necessary.

While many of these roads and bridges were put in place to facilitate the construction of the Four Facilities, it is unknown whether they are in good enough condition to withstand the weight and frequency of trips during deconstruction. As part of the development of

the construction plan, an in depth analysis of bridge and road capacity and state of repair would be conducted by the dam removal entity (DRE), with remedial actions taken prior to the commencement of facility deconstruction.

In addition to the local county roads in the project area, the access ramps to Interstate 5 may also see an increase in heavy construction traffic during deconstruction activities. The increased traffic load could accelerate the rate of wear at these on- and off-ramps, requiring additional maintenance and/or repairs in order to maintain the ramps to existing standards.

Following completion of dam deconstruction additional analysis of road condition would be completed and where needed, as a result of wear generated by deconstruction repairs and or replacement actions would be completed. **Construction traffic could have significant impacts on roads and bridges in the project area. Analysis of road and bridge condition and repair prior to and following dam deconstruction along with implementation of Mitigation Measure TR-1 would reduce any impacts to less than significant.**

Public Transit Effects

Trip volumes and routes of material hauling and worker trips could affect regional transit service. While there are small overlaps between minor haul routes and public transit routes, deconstruction traffic is not expected to interfere with public transit service. **Effects on regional transit service would be less than significant.**

Non-motorized Transportation Effects

Heavy vehicle traffic could cause non-motorized transportation (pedestrian and cyclist) effects. Although the area of analysis has no non-motorized transportation facilities, cyclists and pedestrians might travel along Copco and Topsy Grade/Ager-Beswick Roads in a limited capacity due to the recreational nature of the area. These pedestrians and cyclists would have to travel along the road itself, and could encounter safety hazards when sharing the road with large hauling vehicles, which could occupy much of the available road width, generate dust, or vary speeds around corners. Development of appropriate signage to notify of potential conflicts within the area would reduce this impact by warning drivers and non-motorized users. **The safety hazard for non-motorized transportation would be a less than significant impact.**

Interim Measures

Implementation of the IMs could result in temporary traffic flow effects on I-5, OR66, US97, and access roads. Implementation of several IMs, including IM 7 – J.C. Boyle Gravel Placement and Habitat Enhancement (for seven years) and IM 16 – Water Diversions could result in increased traffic from haul trucks and construction workers; however, any increases in traffic flow would be minor and would not contribute substantially to the number of vehicles on the road. **Traffic flow effects on I-5, OR66, US97, and access roads from implementing the interim measures would be less than significant impact.**

*Implementation of the IMs could cause traffic safety effects associated with sharp turns along Copco Road and OR66. Implementation of several IMs, including IM 7 – J.C. Boyle Gravel Placement and/or Habitat Enhancement, IM 8 – J.C. Boyle Bypass Barrier Removal, and IM 16 – Water Diversions could result in increased traffic from haul trucks and construction workers; however, any increases in traffic flow would be minor and would not contribute substantially to the number of vehicles on the road. **This fact combined with the installation of signage at sharp turns along OR66 and Copco Road would reduce traffic safety effects associated with implementation of the IMs to less than significant.***

Keno Transfer

*The transfer of the Keno Facility to United States Department of the Interior (DOI) could result in effects to traffic and transportation. The Keno Transfer, which is part of the Proposed Action, is a transfer of title for the Keno Facility from PacifiCorp to the DOI. This transfer would not result in the generation of new impacts on transportation compared with existing facility operations. Following transfer of title, DOI would operate the Keno Facility in compliance with applicable law and would provide water levels upstream of Keno Facility for diversion and canal maintenance consistent with agreements and historic practice (KHSA Section 7.5.4). **The transfer of the facility and recreation lands would result in no change from existing conditions from traffic or transportation.***

East and Westside Facilities Decommissioning – Programmatic Measures

*The decommissioning of the East and Westside Facilities could generate adverse traffic and transportation effects. Decommissioning of the East and Westside canals and hydropower facilities of the Link River Dam by PacifiCorp as a part of the KHSA would eliminate the need for diversions at Link River Dam into the two canals. Decommissioning of the facilities would generate some construction traffic. Routes used by this construction traffic would be signed and appropriate safety measures would be incorporated. **Decommissioning the facilities would have less than significant effects on traffic or transportation.***

City of Yreka Water Supply Pipeline Relocation – Programmatic Measures

*Activities associated with relocation of the City of Yreka Water Supply Pipeline and relocation or demolition of recreation facilities could cause traffic safety effects associated with sharp curves along Copco Road and OR66. These construction activities would occur at different times than dam removal deconstruction activities; thus, there would be no overlap in traffic volumes associated with deconstruction of the dams. **This fact combined with the installation of signage at sharp turns along OR66 and Copco Road would reduce traffic safety effects to less than significant.***

Construction activities related to the relocation of the City of Yreka Water Supply Pipeline could result in temporary traffic flow effects on I-5, Copco Road, and access roads. Relocation of the City of Yreka Water Supply Pipeline would occur prior to the start of dam deconstruction.

Therefore, related construction activities for pipeline relocation would take place well before the peak deconstruction activity involved in dam removal. **Traffic flow effects on I-5, Copco Road, and access roads would be less than significant impact.**

KBRA – Programmatic Measures

Construction activities associated implementation of several KBRA programs could cause traffic effects including increases in traffic, the presence of increased numbers of heavy construction equipment, and temporary road closures or detours. The following programs could cause these impacts:

- Phases I and II Fisheries Restoration Plans
- Fisheries Reintroduction and Management Plan
- Wood River Wetland Restoration Project
- On- Project Plan
- Water Use Retirement Program
- Fish Entrainment Reduction
- Klamath River Tribes Interim Fishing Site
- Power for Water Management Program
- Additional Water Conservation and Storage

Construction activities associated with the above-listed KBRA programs could cause temporary traffic effects. KBRA program implementation could result in temporary closures and/or traffic detours associated with culvert upgrades or replacement. In some cases, local access roads could be decommissioned. Minor amounts of vehicular traffic might need to identify alternate routes. Gravel augmentation activities for streambeds could result in gravel deliveries to various locations using dump trucks and placement using backhoes, which could cause traffic flow and safety effects and road condition effects. Construction activities including channel construction, mechanical thinning of trees, road decommissioning, fish passage and facilities construction, breaching levees, and fish hauling could cause temporary increases in traffic and traffic safety effects. It is assumed that construction related to some of these programs could occur on the same roads as the hydroelectric facility removal actions and could contribute to the effects of facility removal on traffic and transportation. **Due to the potentially large amount of construction activities that would occur for the various KBRA programs could generate adverse traffic effects; however, the implementation of best management practices would minimize any traffic impacts to less than significant. Additional traffic analysis and environmental compliance would be completed as appropriate.**

Operational activities associated with the Fisheries Reintroduction and Management Plan could result in temporary traffic effects associated with trap-and-haul activities. Haul trucks would be required to seasonally relocate anadromous fish species around the Keno Impoundment/Lake Ewauna during periods of poor water quality. Haul trucks would carry upstream-migrating fish from the downstream from Keno Dam to areas in Upper Klamath Lake and its tributaries. They would also carry out-migrating fish from Link River Dam to areas downstream from Keno Dam. Haul trucks would increase

traffic on the roads between these sites. Haul trucks may travel on OR66 and US97, access roads, and on-site roads. As shown in Table 3.2-2, area roads carry substantially fewer vehicles in the Proposed Action than the Planning Capacity; additional truck trips for trap and haul operations would not substantially change traffic conditions. Hauling activities would occur after the peak traffic-generating period of facility removal because fish cannot access Keno Dam until after removal of the Four Facilities; however, some construction traffic associated with completing removal activities and reservoir restoration may occur at the same time as hauling operations. Construction traffic related to dam removal and hauling operations, taken together, could increase the severity of the traffic effects, but the combined traffic would likely still be less than the peak traffic during dam deconstruction. The timing of these trap and haul operations from the hydroelectric facility removal actions analyzed above reduce the potential for any negative traffic effects generated by these trap and haul actions from contributing to the effects of facility removal actions. **The traffic flow effects on OR66 and US97, access roads, and on-site roads would be less than significant. Implementation of specific plans and projects described in the KBRA would require future environmental compliance as appropriate.**

3.22.4.2.3 Alternative 3: Partial Facilities Removal of Four Dams Alternative Traffic Flow Effects

Traffic flow effects for the Partial Facilities Removal of Four Dams Alternative would be the same as those for the Proposed Action. **Traffic flow effects on I-5, OR66, US97, and access roads would be a less than significant impact. Traffic flow effects on on-site roads would be a less than significant impact.**

Traffic Safety Effects

Traffic safety effects for the Partial Facilities Removal of Four Dams Alternative would be the same as those for the Proposed Action. **Implementation of Alternative 3 would be less than significant.**

Road Condition Effects

Road condition effects for the Partial Facilities Removal of Four Dams Alternative would be the same as those for the Proposed Action. **Construction traffic could have significant impacts on roads and bridges in the project area. Analysis of road and bridge condition and repair prior to and following dam deconstruction along with implementation of Mitigation Measure TR-1 would reduce any impacts to less than significant.**

Public Transit Effects

Public transit effects for the Partial Facilities Removal of Four Dams Alternative would be the same as those for the Proposed Action. **Implementation of Alternative 3 would be less than significant.**

Non-motorized Transportation Effects

Non-motorized transportation effects for the Partial Facilities Removal of Four Dams Alternative would be the same as those for the Proposed Action. **Implementation of Alternative 3 would be less than significant.**

Keno Transfer

The effects of the Keno Transfer would be the same as those described for the Proposed Action.

East and Westside Facilities Decommissioning – Programmatic Measures

The effects of decommissioning the East and Westside Facilities would be the same as those described for the Proposed Action.

City of Yreka Water Supply Pipeline Relocation – Programmatic Measures

The effects of relocating the City of Yreka Water Supply Pipeline would be the same as those described for the Proposed Action.

KBRA – Programmatic Measures

The Partial Facilities Removal Alternative would include full implementation of the KBRA. Therefore, impacts related to KBRA actions would be the same as under the Proposed Action, discussed above.

3.22.4.2.4 Alternative 4: Fish Passage at Four Dams Traffic Flow Effects

Construction activities associated with the Fish Passage at Four Dams Alternative could result in temporary traffic flow effects on I-5, OR66, US97, access roads, and on-site roads. Under this alternative there would be intermittent construction hauling trips on I-5, OR66, and US97. The only roads experiencing daily heavy vehicle trips would be the local unpaved roads adjacent to each dam. These roads would have 18 daily vehicle trips for fish passage construction, comprised of mainly concrete delivery from nearby batch plants. Material hauling trips would be limited, and worker trips would make up the majority of construction-related traffic. If concrete delivery were not provided at batch plants near the construction sites, then concrete delivery could come from either Klamath Falls, Oregon or the City of Yreka, California. In this case, the estimated 18 daily vehicle trips accounting for concrete delivery would not only access the local roadways, but would be added to traffic on the other major roadways, as shown in Appendix T, 2020 Traffic Volume Projections. The addition of an additional 18 daily vehicle trips to the AADT volumes would not cause deterioration in levels of service.

No long-term or permanent traffic volume increases or long-term changes in traffic patterns would occur as a result of this alternative. Any incremental transportation impacts associated with this alternative would be temporary and would occur during the one-year construction period. The number of construction days at J.C. Boyle and Copco 2 Dams would both be less than 130 days; Copco 1 and Iron Gate Dams would have fewer than 290 construction days.

Traffic associated with this alternative would cause none of the roads in the area of analysis to have a LOS worse than A or a v/c ratio greater than 0.25. The combined total of the projected baseline traffic volumes and the traffic that would result from implementation of this alternative would not exceed the significance criteria for traffic flow impacts. **Traffic flow effects on I-5, OR66, US97, access roads, and on-site roads would be a less than significant impact.**

Implementation of the prescriptions provided by the U.S. Fish and Wildlife Service (USFWS), U.S. Department of the Interior (DOI), and Department of Commerce (DOC) in the Federal Energy Regulatory Commission (FERC) 2007 EIS and seasonal trap and haul operations implemented at Keno Dam could result in temporary traffic flow effects on OR66 and US97, access roads, and on-site roads. Following construction of fishways to provide for volitional fish passage, interim seasonal trap and haul operations would be implemented below Keno Dam to avoid poor water quality conditions in Keno Impoundment/Lake Euwana. As vehicle trips associated with trap and haul operations would take place following fishway construction, there would be no overlap between these trips and peak construction traffic. These activities would be similar to those described above under the Proposed Action in the KBRA Fisheries Reintroduction and Management Plan. **Thus, traffic flow effects on OR66 and US97, access roads, and on-site roads would be less than significant.**

Traffic Safety Effects

Activities associated with the Fish Passage at Four Dams Alternative would cause traffic safety effects at each construction site, on Copco Road, Topsy Grade/Ager-Beswick Road, and on OR66. Traffic safety effects for the Fish Passage at Four Dams alternative would be almost exactly the same as those for the Proposed Action, with two differences: 1) the recreation sites along Copco Road from Iron Gate Dam to Copco Dams would remain open; and 2) construction related traffic would be much lighter than that of the Proposed Alternative. While the traffic volume under this alternative would be lower than under the Proposed Action, the safety impacts would be the same. Installation of signage, dust abatement and proper construction traffic management would minimize impacts. **This impact would be less than significant.**

Activities associated with the implementation of the prescriptions and seasonal trap and haul operations could cause traffic safety effects on OR66 and US97, access roads, and on-site roads. As described under the analysis of traffic flow effects, vehicle trips associated with trap and haul operations would take place following fish passage construction. There would be no overlap between these trips and peak construction traffic. These activities would be similar to those described under the Proposed Action in the KBRA Fisheries Reintroduction and Management Plan. **Thus, traffic flow effects on OR66 and US97, access roads, and on-site roads would be less than significant.**

Road Condition Effects

Road condition effects for the Fish Passage at Four Dams Alternative would be the same as those for the Proposed Action. As part of the development of the construction plan, an in-depth analysis of bridge and road capacity and state of repair would be conducted by

the Hydropower Licensee, with remedial actions taken prior to the commencement of construction. Following completion of construction, additional analysis of road condition would be completed and where needed, as a result of wear generated by construction repairs and or replacement actions would be completed. **Construction traffic could have significant impacts on roads and bridges in the project area. Analysis of road and bridge condition and repair prior to and following construction would reduce any impacts to a less than significant level.**

Public Transit Effects

Public transit effects for the Fish Passage at Four Dams Alternative would be the same as those for the Proposed Action. **Implementation of Alternative 4 would be less than significant.**

Non-motorized Transportation Effects

Non-motorized transportation effects for the Fish Passage at Four Dams Alternative would be the same as those for the Proposed Action. Development of appropriate signage to notify of potential conflicts within the area would reduce this impact by warning drivers and non-motorized users. **The safety hazard for non-motorized transportation would be a less than significant impact.**

Trap and Haul – Programmatic Measures

Operation of trap and haul measures could result in temporary traffic effects. Haul trucks would be required to seasonally relocate anadromous fish species around the Keno Impoundment/Lake Ewauna during periods of poor water quality. Haul trucks would carry upstream-migrating fish from the downstream from Keno Dam to areas in Upper Klamath Lake and its tributaries. They would also carry -migrating fish from Link River Dam to areas downstream from Keno Dam. Haul trucks would increase traffic on the roads between these sites. Haul trucks may travel on OR66 and US97, access roads, and on-site roads. As shown in Table 3.22-2, area roads carry substantially fewer vehicles in the Fish Passage at Four Dams Alternative than the Planning Capacity; adding additional truck trips for trap and haul operations would not substantially change traffic conditions. **The traffic flow effects on OR66 and US97, access roads, and on-site roads would be less than significant.**

3.22.4.2.5 Alternative 5: Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate

Because Copco 1 and 2 Dams are adjacent to one another, they share local access roads, and the greatest traffic effects at either of the dams would apply to both. Under this alternative, the traffic and transportation effects at Iron Gate, Copco 1 and Copco 2 Dams would be the same as Proposed Action and would be less than significant after mitigation, and the traffic and transportation effects at J.C. Boyle Dam would be similar to that of the Fish Passage at Four Dams Alternative and would be less than significant.

Activities associated with the implementation of the prescriptions and seasonal trap and haul operations could cause traffic safety effects on OR66 and US97, access roads, and on-site roads. As described under the analysis of traffic flow effects, vehicle trips

associated with trap and haul operations would take place following dam deconstruction and fishway construction. There would be no overlap between these trips and peak construction-related traffic. These activities would be similar to those described under the Proposed Action in the KBRA Fisheries Reintroduction and Management Plan.

Thus, traffic flow effects on OR66 and US97, access roads, and on-site roads would be less than significant.

Trap and Haul – Programmatic Measures

Operation of trap and haul measures could result in temporary traffic effects. The trap and haul measures around Keno Impoundment/Lake Euwana would have the same impacts under the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative as the Fish Passage at Four Dams Alternative. **The traffic flow effects on OR66 and US97, access roads, and on-site roads would be less than significant.**

City of Yreka Water Supply Pipeline Relocation – Programmatic Measures

The effects of relocating the City of Yreka Water Supply Pipeline would be the same as those described for the Proposed Action.

3.22.4.3 Mitigation Measures

3.22.4.3.1 Mitigation Measures by Consequence Summary

Mitigation Measure TR-1 – Relocate Jenny Creek Bridge and relocate or modify in place as appropriate culverts located along Copco Road away from sediment deposits potentially susceptible to down cutting as a result of reservoir drawdown to prevent bridge foundation failure.

3.22.4.3.2 Effectiveness of Mitigation in Reducing Consequences

All of the mitigation strategies identified herein would reduce potential impacts to less than significant. Other actions that mitigate potential impacts would be standard, best management practices incorporated into project design activities. Such practices include construction zone signing and dust abatement, coupled with the periodic grading of roadways during construction. Implementation of these during project design and construction would reduce potential impacts to less than significant.

3.22.4.3.3 Agency Responsible for Mitigation Implementation

The DRE would be responsible for implementing mitigation measure TR-1.

3.22.4.3.4 Remaining Significant Impacts

Mitigation measures TR-1 would reduce traffic and transportation impacts to less than significant levels.

3.22.4.3.5 Mitigation Measures Associated with Other Resource Areas

Implementation of Mitigation Measure AR-1 could result in temporary traffic flow, traffic safety, and road condition effects on access roads and on-site roads. Mitigation measure AR-1 would relocate mussels in the Hydroelectric Reach and in the Lower Klamath River, downstream from Iron Gate Dam, to tributary streams or upstream of the Hydroelectric Reach. Relocation would take place prior to dam deconstruction activities and reservoir drawdown. Following dam deconstruction, mussels would be moved back

to their approximate location or to other suitable habitat in the river. Given the timing of vehicle trips associated with relocation activities, there would be no overlap with peak construction traffic during dam removal. **Thus, the impact to traffic flow, traffic safety, and road conditions on access roads and on-site roads would be less than significant.**

Implementation of Mitigation REC-1 would create a plan to develop recreational facilities and access points along the newly formed river channel between J.C. Boyle Reservoir and Iron Gate Dam. Recreation facilities, such as campgrounds and boat ramps, currently located on the edge of the reservoir would need to be replaced in appropriate areas near the new river channel once the reservoir is removed. Recreation facility construction would take place following dam deconstruction activities and reservoir drawdown. Given the timing of vehicle trips associated with replacement activities, there would be no overlap with peak construction traffic during dam removal. **Thus, the impact to traffic flow, traffic safety, and road conditions on access roads and on-site roads would be less than significant.**

Several other mitigation measures may require construction, including mitigation measures H-2 (move or elevate structures with flood risk), GW-1 (deepen or replace wells), and WRWS-1 (modify water intakes). These measures could produce vehicle trips associated with construction activities. These activities would take place before or after the primary construction and deconstruction activities associated with the Proposed Action and other alternatives; therefore, they would not add to these construction traffic impacts. These construction activities are generally smaller efforts that would not cause a substantial increase in vehicle trips. **Thus, the impact to traffic flow, traffic safety, and road conditions on access roads, on-site roads, and on roads would be less than significant.**

3.23 Noise and Vibration

This section addresses the noise and vibration impacts of the Proposed Action and alternatives. It includes a description of the area of analysis, the affected environment, and existing conditions. This section also describes the criteria used to define and determine noise and vibration impact significance and the assessment methods. The potential impact from noise and vibration are evaluated for each alternative, and possible mitigation measures are listed. Appendix U describes basic noise and vibration concepts, detailed methods and calculations, and modeling results.

3.23.1 Area of Analysis

The area of analysis for noise and vibration effects associated with the Klamath Hydroelectric Settlement Agreement (KHSA) includes areas near the Four Facilities and the haul routes in Klamath and Jackson Counties, Oregon, and Siskiyou and Shasta Counties, California. Figure 3.23-1 shows the locations of the Four Facilities and haul routes. The area of analysis for the Klamath Basin Restoration Agreement (KBRA) constitutes the entirety of the Klamath Basin.

3.23.2 Regulatory Framework

Noise and Vibration levels in the area of analysis are regulated by local laws and policies. There are no Federal or State regulations applicable to noise and vibration levels from construction activity in the area of analysis.

3.23.2.1 Local Authorities and Regulations

3.23.2.1.1 Siskiyou County General Plan Noise Element (1978)

The Siskiyou County General Plan Noise Element contains criteria for maximum allowable noise levels from construction equipment. Table 3.23-1 lists the maximum allowable noise levels in A-weighted decibels (dBA) for construction equipment applicable to the Proposed Action. There are no other applicable State or local regulatory levels for noise or vibration in the area of analysis.

Although the Proposed Action does not involve highway construction, Federal and State highway traffic noise criteria provide a basis for analyzing project traffic noise impacts. The Federal Highway Administration (FHWA) requires highway agencies to define a “substantial” noise increase as an increase of 5 to 15 dBA over existing noise levels (23 CFR Part 772). The California Department of Transportation (Caltrans) defines “substantial” as a predicted increase greater than or equal to 12 dBA over existing 1-hour equivalent noise levels (L_{eq}) (Caltrans 2006). The Oregon Department of Transportation (ODOT) defines substantial noise increase as greater than or equal to 10 dBA above the existing 1-hour L_{eq} (ODOT 2009).

Notes:

¹ Maximum allowable noise levels from construction equipment at 100 ft from Siskiyou County's General Plan converted to noise levels at 50 ft.

3.23.3 Existing Conditions/Affected Environment

The Lead Agencies identified noise-sensitive human receptor locations (i.e. residences) based on a review of current topographic, aerial, and land use maps. Existing outdoor ambient noise levels at affected sensitive receptor locations were estimated using published average ambient noise levels for various land uses. Siskiyou County presents average noise levels for various land use categories in the Noise Element of their General Plan (Siskiyou County 1978). However these median ambient noise levels for different land use categories were developed based on a one-time field survey in the 1970s and none of the measurements were taken in the project area. Therefore, the Lead Agencies used average daytime L_{eq} and nighttime outdoor L_{eq} noise levels from U.S. Environmental Protection Agency's (USEPA's) *Information on Levels of Environmental Noise Requisite to Protect Public Health and Welfare with an Adequate Margin of Safety* (1974) to estimate ambient noise levels at selected receptor locations. Noise levels for rural residential areas in the USEPA document are lower than the levels presented in the Siskiyou County General Plan; it is more conservative to analyze the impacts using the USEPA levels. Because noise and vibration impacts would not occur without a receptor, the Affected Environment includes the rural residential areas closest to the proposed construction sites. The following paragraphs describe the sensitive receptors in the Affected Environment. Another sensitive receptor is terrestrial wildlife, such as nesting birds. Potential affects to terrestrial wildlife are analyzed in Section 3.5, Terrestrial Resources.

3.23.3.1 Existing Noise Levels near Construction Sites

The land surrounding the J.C. Boyle Dam is primarily undeveloped, and land use is primarily recreational. Recreational sites would be closed to visitors during construction and demolition activities; therefore, no impact analysis was conducted for campgrounds. No residential areas are within a mile of the dam. Because of this, noise and vibration impacts to humans would not occur from construction and deconstruction activities at the J.C. Boyle Dam. Trucks from J.C. Boyle Dam would most likely travel on Oregon Route 66 (OR66), approximately 2,500 feet west of the dam, reached via Topsy Grade Road to access Interstate 5 (I-5) or U.S. Route 97 (US97). Figure 3.23-2 shows the locations of J.C. Boyle Dam, Topsy Campground, Topsy Recreation Site, and Topsy Grade Road.

Copco 1 Dam and Powerhouse are approximately 2,200 feet west of a rural residential area (see Figure 3.23-3). Residences on Janice Avenue are the closest sensitive receptors, and the estimated existing daytime and nighttime outdoor L_{eq} , based on the USEPA information as noted above are 40 and 30 dBA, respectively. The 2,200-foot distance between the dam and the receptor would provide 34 decibels (dB) of noise reduction, based on basic noise propagation calculation as described in Appendix U. The line of sight from the dam to the Janice Avenue receptor is blocked by a hill, the top of which is about 60 feet higher in elevation than the top of Copco 1 Dam at the hill's highest point along the line of sight between the dam and the receptor. The terrain may provide up to 5 dB of additional noise attenuation from the construction site to the Janice Avenue receptors. Copco Road and Topsey Grade Road are the main off-site haul routes from

this construction site. The Lead Agencies estimated traffic noise for trucks transporting materials in and out of the Copco 1 Dam and Powerhouse site via Copco Road and Topsey Grade Road.

Figure 3.23-2. J.C. Boyle Noise Receptors (Closest Receptors to J.C. Boyle Dam).

The closest sensitive receptor to Copco 2 Dam is the residential area on Janice Avenue described above for Copco 1 Dam. From Copco 2 Dam, the receptor is approximately 3,700 feet to the east. The line of sight from the dam to the receptor is blocked by two hills that have elevations approximately 180 feet higher than the top of the dam. Because of this natural topography surrounding the dam and distance between the dam and the receptor, noise from onsite construction activities at Copco 2 Dam would be reduced by 44 dB. No further analysis was conducted on noise from construction equipment and on-site hauling at Copco 2 Dam. The Lead Agencies estimated traffic noise for trucks

transporting materials in and out of Copco 2 Dam via Copco Road and Ager-Beswick Road. Figure 3.23-3 shows the Copco 1 Dam, Copco 1 Powerhouse, and Copco 2 Dam locations as well as the closest sensitive receptor on Janice Avenue.

Figure 3.23-3. Copco 1 and 2 Noise Receptor (Closest Receptor to Copco 1 and Copco 2 Dams).

The Iron Gate Dam area is approximately 1,100 feet east of Copco Road, its main haul route. The closest sensitive receptor to Iron Gate Dam is on Tarpon Drive, approximately 4,500 feet southwest of the dam, as shown on Figure 3.23-4. Based upon the rural residential land use category, the existing daytime outdoor L_{eq} on Tarpon Drive is likely 40 dBA. The existing nighttime outdoor L_{eq} at this receptor is approximately 30 dBA. At its highest point along the line of sight between the receptor and the dam, the hill on river left just upstream of Iron Gate Fish Hatchery is approximately 20 feet lower in elevation than the top of Iron Gate Dam. At the receptor, the hill would provide up to

3 dBA of noise reduction, in addition to the 43 dBA reduction due to distance from the construction site, for a total reduction of 46 dBA. Although this reduction is greater than that for Copco 2 Dam, there would be nighttime construction activities at Iron Gate Dam which may result in significant impact; the Lead Agencies estimated onsite construction and hauling noise levels.

Figure 3.23-4. Iron Gate Noise Receptors (Closest Receptor to Iron Gate Dam).

Section 3.5, Terrestrial Resources, shows the presence of special-status bird and other animal species near each of the dam sites and describes potential impacts and possible mitigation measures related to noise.

Table 3.23-2 summarizes the existing noise levels for the residential receptors selected to assess the noise and vibration impacts from each construction site. Daytime is defined as hours between 7:00 a.m. and 10:00 p.m., and nighttime is defined as 10:00 p.m. to 7:00 a.m. PacifiCorp's residential properties were assumed to be unoccupied during the transfer of ownership to Reclamation and were not considered in this analysis.

Table 3.23-2. Existing Noise Levels at Residential Receptors near Construction Sites

Construction Site ¹	Receptor Description	Distance from Construction Site (feet)	Estimated Existing Daytime L _{eq} (dBA)	Estimated Existing Nighttime L _{eq} (dBA)
Copco 1 Dam	Residential Area on Janice Ave, East of Copco 1 Dam.	2,200	40	30
Copco 2 Dam ²	Residential Area on Janice Ave, East of Copco 1 Dam.	3,700	N/A	N/A
Iron Gate Dam	Residential Area on Tarpon Dr, SW of Iron Gate Dam.	4,500	40	30

Sources: Google Earth; USEPA 1974.

Notes:

¹ There are no applicable receptors at the J.C. Boyle Dam.

² Copco 2 Dam was not analyzed for noise impacts because the reduction in noise level due to distance and terrain between the receptor and the construction site would result in less than significant noise increase at the receptor.

Key:

dBA = A-weighted decibels

L_{eq} = 1-hour equivalent noise level

N/A = not applicable

3.23.3.2 Existing Noise Levels along the Haul Routes

The Lead Agencies used the FHWA Traffic Noise Model, Version 2.5 (TNM2.5) to estimate the existing daytime peak hour L_{eqs} along proposed haul routes. Peak-hour traffic was estimated by multiplying the average daily traffic by 10 percent based on a review of Caltrans and ODOT 2009 average daily and peak hourly traffic data (Caltrans 2010; ODOT 2010). Average daily traffic values published by ODOT (2010) and Caltrans (2010) were used to estimate the existing noise levels on OR66, US97, and I-5. Traffic volumes for I-5 between the City of Yreka and Anderson, California are higher than those for north of the City of Yreka; therefore, for conservative analysis, the lower volumes in the northern portion were used for the baseline. Field observations conducted for the preparation of the Klamath Facilities Removal Environmental Impact Statement/Environmental Impact Report (EIS/EIR) provided the basis for estimating existing 1-hr L_{eq} along Topsy Grade Road, Copco Road, and Ager-Beswick Road.

This analysis uses peak-hour noise level results from TNM2.5 for generic receptors 50 and 500 feet from the edge of the road. Fifty feet represents the minimum distance for a receptor along any roadway and 500 feet is the maximum recommended receptor distance for traffic noise models (Caltrans 2006). Table 3.23-3 summarizes the existing peak hour L_{eq} for project haul routes at 50 feet and 500 feet from the edge of the roadway.

Table 3.23-3. Existing Peak Hour L_{eq} Along Proposed Haul and Commute Routes

Haul Route/Commute Segment	Existing Daytime Peak hour L_{eq} (dBA) ¹	
	50 feet	500 feet
Topsy Grade County Road / Ager-Beswick Road	53	42
US97	75	64
OR66	60	49
Copco Road	58	46
I-5: Between Medford, OR and OR66	77	66
I-5: Between OR66 and the City of Yreka, CA	76	66

Source: Caltrans 2010. ODOT 2010. USEPA 1974.

Notes:

Daytime 1-hour L_{eq} estimated by modeling traffic counts using TNM2.5.

Key:

dBA = A-weighted decibels

L_{eq} = 1-hour equivalent noise level

3.23.3.3 Environmental Consequences

Potential sources of noise from implementation of the KHSA include construction equipment and construction-related traffic noise. Impact determination methods, criteria, and effects determination are presented below.

3.23.3.4 Environmental Effects Determination Methods

This analysis compared the impacts of the Proposed Action and alternatives to the baseline existing conditions. This analysis assumes that no considerable changes in land use would occur in the next 10 years and therefore, existing conditions and the No Action/No Project ambient noise levels would be the same. The Lead Agencies determined noise and vibration levels from construction equipment in the project area and construction-related traffic for each action alternative using the methods described below. A more detailed method description, analysis results, and data supporting the analysis are included in Appendix U.

3.23.3.4.1 On-site Construction Noise

The construction impact analysis focused on outdoor receptors in residential areas near the construction sites. Anticipated sources of construction noise include cranes, excavators, loaders, dozers, concrete trucks, water tankers, pick-up trucks, generators, air compressors, and pavement breakers.

Principles and methods described in FHWA's Roadway Construction Noise Model User's Guide (2006) were the basis for predicting noise impacts associated with construction equipment for the action alternatives. Table 3.23-4 presents noise levels of common construction equipment operating at full power (L_{max}) measured 50 feet from the source, the percentage of time the equipment would be operated at full power (usage factor), and the L_{eq} over a single shift (FHWA 2006). For equipment whose L_{max} in the Roadway Construction Noise Model exceeds the maximum allowable noise levels from construction equipment in the Siskiyou County General Plan Noise Element (1978), the upper limits from Siskiyou County were used.

Table 3.23-4. Construction Operations, Equipment Types, and Their Noise Levels

Equipment Types	Usage Factor	L _{max} at 50 feet (dBA)	L _{eq} at 50 feet (dBA)
Air Compressor	40%	78	74
Backhoe	40%	78	74
Blasting	1%	94	74
Compactor	20%	83	76
Concrete Mixer Truck	40%	79	75
Concrete Pump Truck ¹	20%	81	74
Crane	16%	81	73
Dozers ¹	40%	81	77
Dump Truck	40%	77	73
Excavator	40%	81	77
Front End Loader	40%	79	75
Generator	50%	81	78
Grader	40%	85	81
Jackhammer ¹	20%	81	74
Mounted Impact Hammer (hoe ram)	20%	90	83
Pickup Truck	40%	75	71
Pumps	50%	81	78
Scraper	40%	84	80
Tractor ¹	40%	81	77

Source: FHWA 2006. Siskiyou County 1978.

Notes:

¹Maximum allowable noise levels from construction equipment at 100 ft from Siskiyou County's General Plan converted to noise levels at 50 ft.

Key:

dBA = A-weighted decibels

L_{eq} = 1-hour equivalent noise level

L_{max} = noise levels of equipment operating at full power

Detailed equipment lists for each phase of construction were not available at the time of this analysis. Therefore, the analysis conservatively assumed that the dam removal phase would involve the greatest amount of construction equipment. Attenuation due to sound travel from the source to the receptor was applied to the combined L_{eq} at 50 feet from all equipment, and the approximate noise level from construction at the receptor was added to existing outdoor ambient levels. Noise levels for each dam were analyzed separately because the facilities are spread out. Other phases, such as road and/or bridge improvement, the City of Yreka pipeline construction, implementation of the interim measures, cofferdam construction, drawdown, and removal of recreational facilities, would cause less noise and vibration impacts than on the peak day.

Vibration from Construction Sites

In addition to producing noise, construction activities have the potential to produce vibration that is annoying to humans and may cause damage to structures. Blasting, drilling, and demolition cause the highest levels of vibration from construction projects. Table 3.23-5 presents the peak particle velocity (PPV) in inches per second (in/sec) and

vibration velocity level (L_v) in vibration decibels (VdB) for typical construction equipment (Federal Transit Administration [FTA] 2006). The Lead Agencies applied these levels to each construction site as appropriate and calculated the equivalent PPV and L_v at the receptor. As was done for noise, the PPV and L_v are based on all construction equipment operating simultaneously on peak construction days.

Table 3.23-5 Vibration Levels for Construction Equipment

Equipment Types	PPV at 25 feet (in/sec)	L_v at 25 feet (VdB)
Clam Shovel Drop	0.202	94
Vibratory Roller	0.210	94
Large Bulldozer / Hoe Ram	0.089	87
Caisson Drilling	0.089	87
Loaded Trucks	0.076	86
Jackhammer	0.035	79

Source: FTA 2006.

Key:

in/sec = inches per second

L_v = vibration velocity level

PPV = peak particle velocity

VdB = vibration decibels

Construction-Related Traffic Noise

Transportation noise impacts include noise generated from an increase in local vehicle traffic due to construction workers commuting and trucks hauling waste and construction materials. Details regarding the roadways affected by this Proposed Action are presented in Section 3.22, Traffic and Transportation. Trucks for onsite waste disposal were included in the construction equipment analysis.

Under the Proposed Action, trucks would haul recyclable metal waste to the City of Yreka, California for waste originating in California and to Klamath Falls, Oregon for waste originating in Oregon. Wood waste from Copco 2 Dam would likely be hauled to a hazardous waste landfill in Anderson, California. For construction of fish passages, rebar and wood would be supplied from Medford, Oregon, and concrete would be transported from the City of Yreka, California. The haul routes would likely be I-5, US97, OR66, Copco Road, Ager-Beswick/Ager Road, and Topsy Grade Road. Communities potentially affected by project-related traffic include unincorporated areas of Siskiyou (California) and Klamath (Oregon) Counties and the following cities: the City of Yreka, Montague, Grenada, Weed, Dunsmuir, Mt. Shasta, Redding, and Anderson in California and Klamath Falls, Ashland, Talent, Phoenix, and Medford in Oregon. Figure 3.23-1 shows, for each supplied or removed material type, the haul route and the communities along the haul routes.

Like the trucks, construction workers would commute to the sites using the major highways and roads (I-5, OR66, US97, Copco Road, Ager-Beswick, and Topsy Grade Road). Based on the impact analysis in Section 3.17, Population and Housing, the analysis assumed that workers at facilities in California (Copco 1, Copco 2, and Iron Gate) would commute from Medford, Oregon or the City of Yreka, California and workers at J.C. Boyle Dam would commute from Keno, Oregon and Klamath Falls, Oregon.

This analysis bases the off-site traffic noise impact assessment on the sum of likely existing noise levels near the haul routes, as described in the Affected Environment/Environmental Setting section, and additional traffic noise from the project. Results from TNM2.5 were used for predicting noise levels 50 feet and 500 feet from roadways. This analysis assumes that off-site hauling to suppliers and landfills would only occur during the daytime. Although the worker commute may not overlap with off-site hauling, the number of cars and trucks from worker commute and hauling were added to the baseline traffic counts for a conservative analysis. Nighttime construction at Copco 1 and Iron Gate would have less impact (i.e., only worker commute) than daytime commute and offsite hauling.

3.23.3.5 Significance Criteria

For the purpose of this analysis, a project action would be significant if it resulted in any the following:

- A greater than 10 dBA increase in the daytime or nighttime outdoor 1-hour L_{eq} at the receptor from on-site construction operations
- A PPV greater than 0.3 in/sec at the receptor
- An L_v greater than 72 VdB at the receptor
- A greater than 12 dBA (in California) or 10 dBA (in Oregon) increase above existing 1-hour L_{eq} for traffic-related noise

The criteria above were based on the characteristics of noise, published studies on vibration effects, and established regulations. Although Siskiyou County does not have local significance criteria for noise and vibration levels, the significance criteria itemized above is expected to provide a conservative analysis of noise and vibration levels. Daytime is defined as the hours between 7:00 am and 10:00 p.m., and nighttime is defined as the hours between 10:00 p.m. to 7:00 a.m. A 10 dBA increase in noise level is perceived as a doubling of noise (FHWA 2011). A PPV of 0.3 in/sec or greater can damage old residential structures from continuous or frequent vibration sources (Jones and Stokes 2004). The annoyance level for vibration is 72 VdB in residential areas (FTA 2006). Caltrans (2006) and ODOT (2009) define a substantial increase in noise levels from traffic as an increase of 12 dBA or 10 dBA, in California and Oregon, respectively, above existing 1-hour L_{eq} .

3.23.3.6 Effects Determinations

The following sections describe the noise and vibration impacts for each alternative.

3.23.3.6.1 Alternative 1: No Action/No Project

The Four Facilities would not be removed and fish passages would not be constructed.

This analysis assumes that ambient noise levels under the No Action/No Project Alternative would be the same as existing conditions. **Therefore, implementation of the No Action/No Project Alternative would cause no change from existing conditions from construction noise impacts.**

Several ongoing resource management actions could cause noise and vibration impacts.

There may be some noise and vibration effects due to the use of construction equipment throughout the basin associated with ongoing resource management actions, including the Fish Habitat Restoration Program. These activities may include mechanical thinning of vegetation, gravel augmentation, and breaching levees. Although sufficient information is currently not available to estimate noise and vibration impacts, the quantity of equipment required to complete these restoration activities are expected to be less than the required equipment for dam removal and fish ladder construction activities. **Noise and vibration impacts from ongoing resource management actions are therefore assumed to be less than significant.**

3.23.3.6.2 Alternative 2: Full Facilities Removal of Four Dams (Proposed Action)

This section summarizes the noise and vibration effects that would be caused by removing the dams, powerhouses, and other associated structures. J.C. Boyle Dam was not analyzed relative to impacts to human receptors because there are no applicable human sensitive receptors within a 1-mile radius. Copco 2 Dam was also not analyzed for human receptor noise impacts because the line of sight between the dam and the receptor is completely blocked by the terrain, and the nearest sensitive receptor is 3,700 feet from the dam. Impacts to special-status bird species identified near J.C. Boyle Dam and Copco 2 Dam are discussed in further detail below, as well as in Section 3.5, Terrestrial Resources. The Proposed Action impacts are expected to occur between January and September 2020 for approximately four to six months during the scheduled peak dam removal at each site. There are no long-term noise and vibration impacts due to the Proposed Action.

Construction Equipment Noise and Vibration

Two shifts of construction workers are expected to carry out deconstruction of Copco 1 and Iron Gate Dams. Both work shifts overlap with daytime (7:00 a.m. to 10:00 p.m.) and nighttime (10:00 p.m. to 7:00 a.m.) existing levels defined in the previous section. The shifts are described further below. Table 3.23-6 lists the predicted average 1-hour L_{eq} at each construction site and receptor, the increase in noise level at the receptor that would occur as a result of the Proposed Action, and the times of day when the significant impact is expected to occur.

Table 3.23-6. Summary of Noise Levels from Deconstruction Activities for the Proposed Action

Location ¹	L _{eq} (dBA)		
	At Construction Site (50 feet)	At Receptor with Proposed Action	Increase in L _{eq} Caused by Proposed Action
Copco 1 Dam Daytime ²	88-91	50-52	10-12
Nighttime ³	88-91	49-52	10-22
Iron Gate Dam Daytime ²	91	46	6
Nighttime ³	91	44-46	6-14

Source: FHWA 2006.

Notes:

¹ J.C. Boyle Dam removal was not analyzed because there are no receptors within 1 mile. Copco 2 Dam removal was not analyzed because the line of sight to the closest receptor is completely blocked.

² Daytime is defined as between the hours of 7:00 a.m. to 10:00 p.m.

³ Nighttime is defined as between the hours of 10:00 p.m. to 7:00 a.m.

Key:

dBA = A-weighted decibels

L_{eq} = 1-hour equivalent noise level

Deconstruction activities at the Four Facilities could cause a temporary increase in noise levels at Copco 1 Dam that could affect residents in the area. The predicted shift-period L_{eq} from all construction equipment on a peak construction day at Copco 1 is 91 dBA at 50 feet during the first shift (6:00 a.m. to 3:00 p.m.) and 88 dBA during the second shift (3:00 p.m. to midnight). Attenuation due to distance, topography, and the atmosphere would reduce these construction site L_{eq} by approximately 39 dBA at the nearest receptor. Compared to the daytime (7:00 a.m. to 10:00 p.m.) and nighttime (10:00 p.m. to 7:00 a.m.) existing outdoor noise levels of 40 and 30 dBA, the resulting increases range from less than 10 to 22 dBA, depending on the time of day. The first shift exceeds the significance criteria at all times because of the high source noise level. The second shift only exceeds the significance criteria after 10:00 p.m. when the background noise levels are expected to be very low. **This increase in outdoor noise levels would have a temporary significant noise impact on the residential area near Copco 1 Dam. Mitigation Measure NV-1 would be implemented but would not reduce outdoor noise impacts to less than significant levels at sensitive receptors; therefore noise impacts would remain significant and unavoidable for outdoor receptors during Copco 1 Dam deconstruction.**

Deconstruction activities at the Four Facilities could cause a temporary increase in nighttime noise levels at Iron Gate Dam. The predicted shift-period L_{eq} from the Iron Gate facilities removal is 91 dBA at 50 feet during both shifts (7:00 a.m. to 4:00 p.m. and 4:00 p.m. to 11:00 p.m.). The combination of existing noise, distance divergence, topographic attenuation, and atmospheric attenuation would result in a shift-period L_{eq} of 46 dBA during the daytime (7:00 a.m. to 10:00 p.m.) and 44 dBA during the nighttime (10:00 p.m. to 11:00 p.m.) at the nearest receptor. The estimated noise level at the receptor exceeds the significance criterion for nighttime noise. **Deconstruction noise**

would cause a temporary significant noise impact on the residential area near Iron Gate Dam at night. Mitigation Measure NV-1 would be implemented but would not reduce nighttime outdoor noise impacts to less than significant levels at sensitive receptors. Nighttime noise impacts would remain significant and unavoidable for outdoor receptors during Iron Gate nighttime deconstruction.

Reservoir restoration activities could result in short-term increases in noise levels in the project vicinity. Additional equipment, including hydro seeding barges, trucks, and helicopters, would be used for reservoir restoration at the same time as dam deconstruction. This reservoir restoration activity would add to the noise levels generated by dam deconstruction activities in and around the dam sites described above. Additionally residential areas along Copco and Iron Gate Reservoirs away from the dam deconstruction sites may experience temporary increased noise levels due to passing hydro seeding vessel or vehicle along the embankment. Aerial hydro seeding is scheduled to begin on March 15 and last for 10 days at Iron Gate and 20 days at Copco. The helicopter would make 30 trips per day between the hours of 7:30 a.m. and 7:00 p.m. All other hydro seeding would be accomplished by barges and trucks. **Helicopters and other equipment noise from embankment restoration would cause a temporary significant noise impact on the residential areas near Copco and Iron Gate Reservoirs and increase the significant noise levels generated by dam deconstruction in and around the dam sites. Mitigation Measure NV-1 would be implemented but would not reduce outdoor noise impacts to less than significant levels at these sensitive receptors.**

Blasting activities at Copco 1 Dam could increase vibration levels. Table 3.23-7 summarizes the Proposed Action's vibration levels at sensitive receptors. Because of blasting, during the first shift at Copco 1 Dam, the PPV and L_v at the nearest receptor are 0.065 in/sec and 84 VdB, respectively. For reference, vibration levels without blasting are shown in Table 3.23-7. The first shift at Copco 1 Dam would therefore exceed the significance criteria for L_v and this is because of the substantial amount of blasting required. During the second shift, the maximum PPV for this alternative would be 0.001 in/sec at the receptors and the L_v at the receptors would be approximately 48 VdB. The vibration levels from Iron Gate Dam and Copco 2 Dam or during the second shift from Copco 1 Dam would not exceed the significance criteria of 0.3 in/sec and 72 VdB. **Deconstruction activities would result in significant human annoyance levels for vibration impacts at receptors near Copco 1 Dam during blasting operations in the first shift. Mitigation Measure NV-1 would be implemented but would not reduce vibration impacts to less than significant levels; therefore, vibration impacts to humans would remain significant and unavoidable during blasting at Copco 1.**

Deconstruction-Related Traffic Noise

Transporting waste to off-site landfills and construction worker commutes could cause increases in noise along haul routes. Noise effects from transporting waste and construction worker commute were evaluated for receptors at 50 feet and 500 feet from the road. Table 3.23-8 shows the results of the TNM2.5 modeling for this potential impact. The TNM2.5 results showed only minor increases in existing L_{eq} for receptors

50 feet or more from all haul routes analyzed. Increases in traffic from construction worker commutes for the second shift at Copco 1 and Iron Gate would result in less noise impact than that presented in Table 3.23-8. **Transporting waste off-site and construction worker commutes would result in less than significant noise impacts for receptors 50 feet or more from all local roadways.**

Table 3.23-7. Summary of Vibration from Construction Activities for the Proposed Action

Source ¹	PPV at Receptor (in/sec)	L _v at Receptor (VdB)
Copco 1 Dam		
Shift 1	0.065 (0.002 without blasting)	84 (53 without blasting)
Shift 2	0.001	47
Copco 2 Dam	0.001	48
Iron Gate Dam		
Shift 1	0.001	48

dBA = A-weighted decibels

L_{eq} = 1-hour equivalent noise level

ft = feet

Keno Transfer

The transfer of Keno Facility to the United States Department of the Interior (DOI) could have adverse effects on noise and vibration. The Keno Transfer is a transfer of title for the Keno Facility from PacifiCorp to the DOI. This transfer would not result in the generation of new impacts on noise and vibration compared with existing facility operations. Following transfer of title, DOI would operate Keno in compliance with applicable law and would provide water levels upstream of Keno Dam for diversion and canal maintenance in accordance with agreements and historic practice (KHSA Section 7.5.4). **Therefore, the Keno Transfer would have no change from existing conditions for noise and vibration.**

East and Westside Facility Decommissioning – Programmatic Measures

The decommissioning of the East and Westside Facilities could have adverse effects on noise and vibration. Decommissioning of the East and Westside canals and hydropower facilities of the Link River Dam by PacifiCorp as a part of the KHSA will eliminate the need to divert water at Link River Dam in to the two canals. The decommissioning and deconstruction activities could create noise and vibration in excess of applicable standards depending on the location of nearby sensitive receptors. Surveys of receptors and specific decommissioning activities will need to be completed prior to the decommissioning in order to prevent adverse impacts to sensitive receptors. **Therefore, the decommissioning of the East and Westside Facilities would have a less than significant effect on noise and vibration.**

KBRA – Programmatic Measures

The KBRA has several programs that could cause temporary increases in noise and vibration level. The following KBRA programs may cause some noise and vibration impacts from the use of heavy equipment:

- Phases I and II Fisheries Restoration Plans
- Fisheries Reintroduction and Management Plan
- Wood River Wetland Restoration
- On-Project Plan
- Water Use Retirement Program
- Fish Entrainment Reduction
- Power for Water Management Program
- Additional Water Conservation and Storage

Construction activities associated with the KBRA could cause temporary increases in noise and vibration levels. Construction activities associated with the above KBRA programs include channel construction, mechanical thinning of trees, road decommissioning, fish passage and facilities construction, breaching levees, and fish hauling. While the exact geographic location and timing of these programs is not known, it is assumed that some could occur at the same time and in the same area as the hydroelectric facility removal actions analyzed above and could contribute to the effects of facility removal on noise and vibration. **Due to the potentially large amount of**

construction activities that would occur for the various KBRA programs, it is anticipated that the effects from noise and vibration could be potentially significant on sensitive receptors. Mitigation Measure NV-1 would be expected to reduce noise and vibration impacts to less than significant levels; therefore, noise vibration impacts to humans would be expected to be reduced to a less than significant impact. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.

*Operational activities associated with the Fisheries Reintroduction and Management Plan could result in temporary increases in noise and vibration levels from vehicles associated with trap-and-haul activities. Haul trucks relocating anadromous fish species around Keno Impoundment /Lake Eauwna could produce noise and vibration. Seasonal trap and haul operations would occur below Keno Dam and near Link River Dam during periods of poor water quality. Hauling activities would occur after the peak noise-generating period of facility removal because fish cannot access Keno Dam until after removal of the Four Facilities; however, some noise and vibration associated with completing removal activities and reservoir restoration may occur at the same time as hauling operations. Construction noise and vibration related to dam removal and hauling operations, taken together, could increase the severity of the effects, but the combined noise and vibration would likely still be less than the peak levels during dam deconstruction. The timing of these trap and haul operations from the hydroelectric facility removal actions analyzed above reduce the potential for any negative noise and vibration effects generated by these trap and haul actions from contributing to the effects of facility removal actions. **Although the exact extent and timing of these hauling activities is not known, it is anticipated that the effects from noise and vibration could be potentially significant on sensitive receptors (including the Topsy Campground near Keno Dam). Mitigation Measure NV-1 would be expected to reduce noise and vibration impacts to less than significant levels; therefore, noise vibration impacts to humans would be expected to be reduced to a less than significant impact. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.***

3.23.3.6.3 Alternative 3: Partial Facilities Removal of Four Dams

Under this alternative, short-term demolition activities and drawdown of reservoirs would still occur; however, only in-stream facilities and select ancillary facilities would be demolished. Although there would be less total construction work and material hauling, peak day operations would be similar to those of the Proposed Action.

*Deconstruction activities at the Four Facilities could increase noise and vibration levels. Noise and vibration impacts would be the same as for the Proposed Action and would be significant for construction noise and vibration impacts. **Mitigation Measure NV-1 would be implemented but would not reduce outdoor noise impacts to less than significant levels at sensitive receptors. Noise impacts would remain significant and unavoidable for outdoor receptors near Copco 1 and Iron Gate. Equipment noise from embankment restoration would cause a temporary significant noise impact on the residential areas near Copco Lake and Iron Gate Reservoir. Vibration impacts***

to humans would remain significant and unavoidable during blasting at Copco 1. Transporting waste to off-site landfills and construction worker commutes would result in a less than significant noise impact for receptors 50 feet or more from all local roadways.

Keno Transfer

The effects of the Keno Transfer would be the same as those for the Proposed Action.

East and Westside Facility Decommissioning – Programmatic Measures

The effects of the East and Westside Facilities removal would be the same as those described for the Proposed Action.

KBRA – Programmatic Measures

The Partial Facilities Removal Alternative would include full implementation of the KBRA. Therefore, impacts related to KBRA actions would be the same as under the Proposed Action, discussed above.

3.23.3.6.4 Alternative 4: Fish Passage at Four Dams

This section summarizes the potential noise and vibration impacts from constructing a fish passage at the Four Facilities. J.C. Boyle Dam was not analyzed for this alternative because there are no applicable sensitive receptors within a 1-mile radius. Copco 2 Dam was also not analyzed because the line of sight between the dam and the receptor is completely blocked by hills.

Construction Equipment Noise and Vibration

Construction activities at the Four Facilities could cause a temporary increase in noise levels at Copco 1 and Iron Gate receptor sites. Table 3.23-9 summarizes the predicted average 1-hour L_{eq} at each construction site and receptor, and the temporary increase in noise level at the receptor that would occur as a result of the Fish Passage at Four Dams Alternative. There are no long-term noise and vibration impacts due to this alternative.

Table 3.23-9. Summary of Noise Levels from Construction Activities for the Fish Passage at Four Dams Alternative

Location ¹	1-Hour L _{eq} (dBA)		
	At Construction Site (50 feet)	At Receptor with Fish Passage Construction	Increase in Existing L _{eq} Caused by Fish Passage Construction
Copco 1 Dam	90	52	12
Iron Gate Dam	90	45	5

Source: FHWA 2006.

Notes:

¹ J.C. Boyle was not analyzed because there are no receptors within 1 mile. Copco 2 Dam was not analyzed because the line of sight to the closest receptor is completely blocked.

Key:

dBA = A-weighted decibels

L_{eq} = 1-hour equivalent noise level

Fish passage construction activities could cause a temporary increase in noise levels at Copco 1 Dam. The predicted shift-period L_{eq} from construction activities at Copco 1 Dam is 90 dBA at 50 feet. Attenuation offered by distance, topography, and the atmosphere would reduce this L_{eq} to approximately 52 dBA at the nearest receptor. The resulting increase in ambient noise levels at the receptor would be 12 dBA. **This increase in ambient noise levels would represent a significant noise impact on the residential area near Copco 1 Dam. Mitigation Measure NV-1 would be implemented but would not reduce outdoor noise impacts to less than significant levels at sensitive receptors. Noise impacts would remain significant and unavoidable for outdoor receptors during construction.**

Fish passage construction activities could cause a temporary increase in noise levels at Iron Gate Dam. The predicted shift period L_{eq} from construction activities at Iron Gate Dam is 90 dBA at 50 feet. Attenuation offered by distance, topography, and the atmosphere would reduce this 1-hour L_{eq} to approximately 45 dBA at the nearest receptor. The resulting increase in ambient noise levels at the receptor would be 5 dBA. **This increase in ambient noise levels would result in a less than significant noise impact on the residents near Iron Gate Dam.**

Construction activities could increase vibration levels. Table 3.23-10 summarizes vibration levels at the receptors for the Fish Passage at Four Dams Alternative. The maximum PPV for this alternative would be 0.003 in/sec at the receptor near Copco 1 Dam. The L_v at the receptors would range from 46 to 57 VdB for different vibration source locations; these vibration levels would not exceed the 0.3 in/sec and 72 VdB significance criteria. **Construction activities would result in less than significant vibration impacts.**

Table 3.23-10. Summary of Vibration Levels at Receptors from Construction Activities for the Fish Passage at Four Dams Alternative

Location ¹	Peak Particle Velocity (in/sec)	Vibration Velocity Level (VdB)
Copco 1 Dam	0.003	57
Copco 2 Dam	0.001	48
Iron Gate Dam	0.001	46

Source: FTA 2006.

Notes:

¹ J.C. Boyle was not analyzed because there are no receptors within 1 mile.

Key:

VdB = vibration decibels

in/sec = inches per second

Construction-Related Traffic

Transporting construction materials from off-site suppliers and construction worker commute could cause increases in noise along haul routes. The Lead Agencies evaluated

the noise effects of transporting materials to the construction sites for receptors at 50 feet and 500 feet from the road. Table 3.23-11 shows the results of the TNM2.5 modeling for this potential impact. The TNM2.5 results showed only minor increases in existing L_{eq} for receptors 50 feet or more from all haul routes analyzed. **Transporting construction materials from off-site suppliers and construction worker commute would have a less than significant impact on receptors 50 feet or more from all local roadways.**

Table 3.23-11. Summary of Construction-Related Traffic Noise from Off-site Hauling for the Fish Passage at Four Dams Alternative

Haul Route/Commute Segment	Peak 1-hour L_{eq} (dBA)		Increase in Existing L_{eq} Caused by Fish Passage Construction (dBA) ¹	
	50 ft	500 ft	50 ft	500 ft

I-5: Between Medford, OR and OR66	77	66	0	0
Ager-Beswick Road	54	43	3	3
Copco Road	60	49	2	2
I-5: Between OR66 and the City of Yreka, CA	77	66	0	0

Notes:

¹ The increase in L_{eq} may appear different when subtracting the existing 1-hour L_{eq} from peak 1-hour L_{eq} values due to rounding.

Key:

dBA = A-weighted decibels

L_{eq} = existing 1-hour equivalent noise level

ft = feet

Trap and Haul – Programmatic Measures

Trap and Haul operations could result in temporary increases in noise and vibration levels from vehicles used to relocate fish. Haul trucks relocating anadromous fish species around Keno Impoundment/Lake Euwana could produce noise and vibration. Seasonal trap and haul operations would occur below Keno Dam and near Link River Dam during periods of poor water quality. Although the exact extent and timing of these hauling activities is not known, it is anticipated that the effects from noise and vibration could be potentially significant on sensitive receptors (including the Topsy Campground near Keno Dam). Mitigation Measure NV-1 would be expected to reduce noise and vibration impacts to less than significant levels; therefore, noise vibration impacts to humans would be expected to be reduced to a less than significant impact. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.

3.23.3.6.5 Alternative 5: Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Dams

This section summarizes the noise and vibration impacts that would be caused by constructing a fish passage at J.C. Boyle and Copco 2 Dams and removing the facilities at

the Copco 1 and Iron Gate Dams. The analysis for this alternative does not predict construction impacts at J.C. Boyle Dam because there are no applicable receptors. Copco 2 Dam was also not analyzed for noise impacts because the line of sight between the dam and the receptor is completely blocked by hills.

Construction Equipment Noise and Vibration

Construction and deconstruction activities could cause a temporary increase in noise and vibration levels at receptor sites. Noise and vibration impacts at Copco 1 and Iron Gate Dams would be the same as for the Proposed Action. Vibration impacts near Copco 2 would be the same as for the Fish Passage at Four Dams Alternative. Increased noise and vibration levels would occur only during the construction/deconstruction period; no long-term noise and vibration impacts would occur. **Deconstruction at Copco 1 and Iron Gate Dams would have a temporary significant noise impact on outdoor receptors near the dam. Vibration impact to humans would be significant near Copco 1 Dam during blasting. Vibration impacts would be less than significant at receptors near Iron Gate and Copco 2 Dams. Equipment noise from embankment restoration would have a temporary significant noise impact on the residential areas near Copco and Iron Gate Reservoirs. Mitigation Measure NV-1 would be implemented but would not reduce outdoor noise and/or vibration impacts to less than significant levels at sensitive receptors near Copco 1 and Iron Gate Dams. Noise impacts would remain significant and unavoidable for outdoor receptors. Vibration impacts would also remain significant and unavoidable to humans near Copco 1.**

Construction-Related Traffic

Transporting waste to off-site landfills, hauling construction materials from off-site suppliers, and construction worker commute could cause increases in noise along haul routes. Noise impacts from haul trucks and worker commute were evaluated for receptors at 50 feet and 500 feet from the road. Table 3.23-12 shows the results of the TNM2.5 modeling for this alternative. The TNM2.5 results showed only minor increases in existing L_{eq} for receptors 50 feet or more from all haul routes analyzed. The second shift at Copco 1 and Iron Gate would not impact the roads in Oregon and would cause less impact on the California roads than what is presented in Table 3.23-12.

Transporting waste and construction materials and construction worker commute would have a less than significant impact on receptors 50 feet or more from all local roadways.

Trap and Haul – Programmatic Measures

Trap and Haul operations could result in temporary increases in noise and vibration levels from vehicles used to relocate fish. The trap and haul measures around Keno Impoundment/Lake Euwana would have the same impacts under the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative as the Fish Passage at Four Dams Alternative. Although the exact extent and timing of these hauling activities is not known, it is anticipated that the effects from noise and vibration could be potentially significant on sensitive receptors (including the Topsy Campground near Keno Dam). Mitigation Measure NV-1 would be expected to reduce noise and vibration

impacts to less than significant levels; therefore, noise vibration impacts to humans would be expected to be reduced to a less than significant impact. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.

Table 3.23-12. Summary of Construction-Related Traffic Noise from Off-site Hauling for the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative

Haul Route/Commute Segment	Peak 1-hour L_{eq} (dBA)		Increase in Existing L_{eq} Caused by Fish Passage Construction or Facilities Removal (dBA) ¹

Key:

ft = feet

dBA = A-weighted decibels

3.23.3.7 Mitigation Measures

The following sections describe the recommended noise and vibration mitigation measures for each alternative.

3.23.3.7.1 Mitigation Measure by Consequences Summary

Mitigation Measure NV-1 – The Dam Removal Entity (DRE) will develop a Noise and Vibration Control Plan (NVCP) to address increased day and night time noise levels as a result of the Proposed Action. The NVCP will identify the procedures for predicting construction noise levels at sensitive receptors prior to performing construction activities and will describe the reduction measures required to meet the target noise level. The NVCP will be based on planned construction activities. Noise and vibration mitigation measures will include, but will not be limited to the following:

- The DRE will ensure that the Construction Contractor is maintaining equipment to comply with noise standards (e.g., exhaust mufflers, acoustically attenuating shields, shrouds, or enclosures).
- For nighttime or after-hour construction, the DRE will coordinate with the local jurisdictions to minimize noise. Nearby residents will be notified of hours and duration of construction activities.

- Schedule truck loading, unloading, and hauling operations so as to reduce daytime and nighttime noise impacts to less than noticeable levels.
- The blasting schedule will be coordinated with local jurisdictions to minimize noise. Nearby residents will be notified of blasting schedules.
- Appropriate blasting techniques will be employed to minimize noise and vibration.
- Noise and vibration complaints will be addressed promptly by the DRE and high impact activities rescheduled or alternate means of demolition and construction implemented, when feasible.

3.23.3.7.2 Effectiveness of Mitigation in Reducing Consequences

Implementation of mitigation measure NV-1 would manage noise and vibration impacts but would not reduce to less than significant levels. Because of the large construction areas and the long distances between the construction site and the receptors, conventional methods to reduce noise source, such as constructing barriers, would not provide a substantial reduction in noise levels and would not reduce noise and vibration to less than significant levels.

3.23.3.7.3 Agency Responsible for Mitigation Implementation

The DRE will be responsible for implementing mitigation measure NV-1.

3.23.3.7.4 Remaining Significant Impacts

Mitigation measures presented in Section 3.23.5 would not reduce noise impacts to less than-significant levels for outdoor receptors. This is because of the very low existing noise levels at the receptor compared to the high noise levels at the construction site. However, actual existing daytime and nighttime ambient noise levels may be higher than those used in this analysis and construction noise levels may be lower and therefore the impact may be less. This analysis calculated outdoor noise levels at residential properties. A review of the parcel lots near each dam site indicated that the following parcels are located within a one-mile radius of each dam site, as shown in Figures 3.23-5 and 3.23-6, and may be affected by noise:

- Iron Gate: 40 parcels, excluding Federal, county, and PacifiCorp Properties
- Copco 1 and 2: 135 parcels, excluding Federal, county, and Pacific Power and Light Properties

It is not known at this time how many parcels would be occupied during construction and demolition activities; therefore it is assumed all parcels would contain residents and would be affected. The majority of parcels, however, are located farther from the construction sites than the peak sensitive receptor, so any potential impacts would be less than what was estimated for the peak receptor.

As described earlier, all calculated noise levels are for outdoor human receptors. Buildings with an open window would reduce the noise levels indoors by 10 dB. A light frame building with a closed ordinary sash would reduce the outdoor noise level by

20 dB. Depending on the building and window types, up to 35 dB reduction in indoor levels may be achieved (FHWA 2011), substantially reducing impacts for indoor receptors.

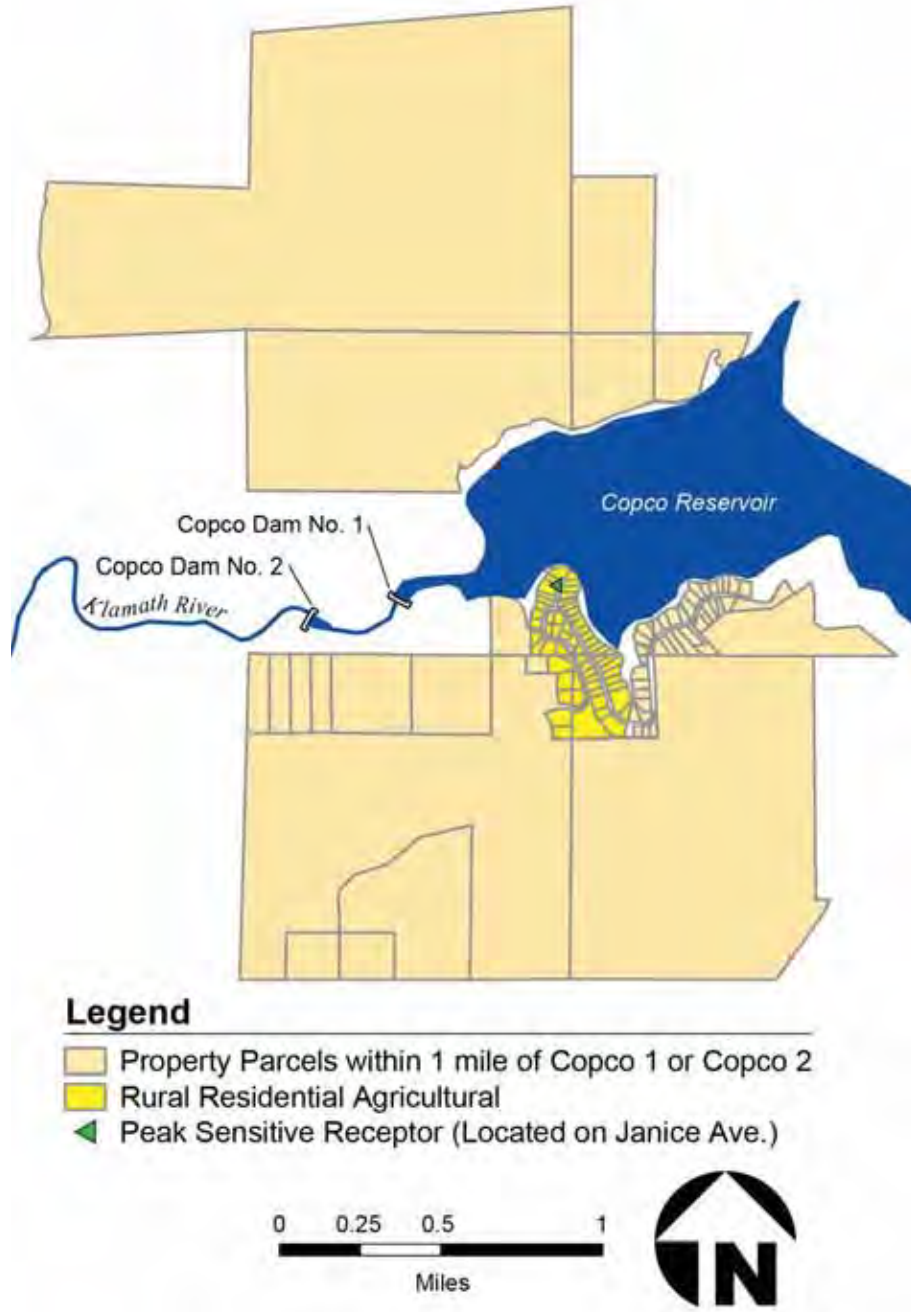

Figure 3.23-5. Parcel Lots within One-Mile of Copco 1 and 2 Dams.

Figure 3.23-6. Parcel Lots within One-Mile of Iron Gate Dam.

Mitigation Measures Associated with Other Resource Areas

Transporting fish and mollusks under Mitigation Measures AR-1, 2, 5-7 could cause temporary increases in traffic noise. These mitigation measures involve trap and haul of fish and mollusks to protect them from the reservoir drawdown and dam deconstruction activities. It is anticipated that as many as 150 truck trips may be required to transport juvenile fish from areas downstream from Iron Gate Dam to the confluence of Klamath and Trinity Rivers between February and April of 2020. On average, the traffic volume during peak construction times would increase by two trucks due this mitigation measure. As a rule of thumb, for traffic noise levels to increase significantly, hourly traffic volume must multiply by approximately a factor of 10. **The noise and vibration impacts of these measures would be less than significant.**

Construction activities under Mitigation Measure TR-1 could cause a temporary increase in noise and vibration levels. Relocation of Jenny Creek Bridge and culverts near Iron Gate Reservoir would occur before the other construction phases of dam removal. In comparison to the dam removal, equipment and time required for this construction would be minimal. No sensitive receptors were identified near the bridge and therefore, noise and vibration from construction would not impact human receptors. **Construction noise and vibration due to TR-1 would be less than significant.**

Construction activities under Mitigation Measure REC-1 could cause a temporary increase in noise and vibration levels. Mitigation REC-1 would create a plan to develop recreational facilities and access points along the newly formed river channel between J.C. Boyle Reservoir and Iron Gate Dam. Recreation facilities, such as campgrounds and boat ramps, currently located on the edge of the reservoir would need to be replaced in appropriate areas near the new river channel once the reservoir is removed. In comparison to the dam removal, equipment and time required for this construction would be minimal. Recreation facility replacement would occur following dam removal and would not generate noise levels that exceed levels anticipated for the peak day. **Construction noise and vibration due to REC-1 would be less than significant.**

Several other mitigation measures may require construction, including mitigation measures H-2 (move or elevate structures with flood risk), GW-1 (deepen or replace wells), and WRWS-1 (modify water intakes). These measures could produce noise and vibration associated with construction activities. These activities would take place before or after the primary construction and deconstruction activities associated with the Proposed Action and action alternatives; therefore, they would not add to these noise and vibration impacts. The construction activities are generally smaller efforts that would not cause a substantial increase in noise to sensitive receptors. **Construction-related mitigation measures would cause a less than significant noise and vibration impact to sensitive receptors.**

Chapter 4

Cumulative Effects

This chapter describes the cumulative effects of the Proposed Action and alternatives. Included here are descriptions of the regulatory requirements, methods, and past, present, and reasonably foreseeable future actions considered as part of the analysis.

4.1 Cumulative Effects Overview

Cumulative effects are those environmental effects that, on their own, may not be “significant” (National Environmental Policy Act [NEPA]) or “considerable” (California Environmental Quality Act [CEQA]), but when combined with similar effects over time, result in “significant” (NEPA) or “considerable” (CEQA) effects. Cumulative impacts result when the effects of an action are added to or interact with other effects in a particular place and within a particular time. It is the combination of these effects, and any resulting environmental degradation, that should be the focus of cumulative impact analysis. While impacts can be differentiated by direct, indirect, and cumulative, the concept of cumulative impacts takes into account all disturbances since cumulative impacts result in the compounding of the effects of all actions over time. Thus the cumulative impacts of an action can be viewed as the total effects on a resource, ecosystem, or human community of that action and all other activities affecting that resource no matter what entity (Federal, non-Federal, or private) is taking the actions (EPA 315-R-99-002/May 1999). Cumulative effects are an important part of the environmental analysis because they allow decisionmakers to look not only at the impacts of an individual proposed project, but the overall impacts on a specific resource, ecosystem, or human community over time from several different projects.

4.1.1 Regulatory Requirements

Both the NEPA and the CEQA require consideration of cumulative effects in an Environmental Impact Statement/Environmental Impact Report (EIS/EIR). The National Historic Preservation Act (NHPA) requires consideration of cumulative effects to historic properties.

4.1.1.1 *National Environmental Policy Act*

Cumulative effects are defined as “the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions, regardless of what agency (Federal or non-Federal) or person undertakes such actions (40 CFR Section 1508.7).”

NEPA regulations require an analysis of direct, indirect, and cumulative effects and define “effects” as “ecological (such as the effects on natural resources and on the components, structures, and functioning of affected ecosystems), aesthetic, historic, cultural, economic, social, or health, whether direct, indirect, or cumulative (40 CFR Section 1508.8).” In addition, the NEPA regulations state that when determining the scope of an EIS, both connected and cumulative actions must be discussed in the same document as the Proposed Action (40 CFR Section 1508.25(a)(1) and (2)).

4.1.1.2 National Historic Preservation Act

The regulations for Section 106 of the NHPA define “adverse effect” as an undertaking that “may alter, directly or indirectly, any of the characteristics of a historic property that qualify the property for inclusion in the National Register in a manner that would diminish the integrity of the property’s location, design, setting, materials, workmanship, feeling, or association.” (36 CFR Section 800.5(a)(1)). “Adverse effects” explicitly include “reasonably foreseeable effects caused by the undertaking that may occur later in time, be farther removed in distance or be cumulative.” (36 CFR Section 800.5(a)(1)). Cumulative effect under Section 106 of the NHPA applies only to those resources that are listed in or eligible for the National Register. Much of the analysis regarding potential cumulative adverse effects to historic properties, including proposed mitigation measures, is discussed in Chapter 3.13, Cultural Resources.

4.1.1.3 California Environmental Quality Act

Cumulative effects are defined in the CEQA Guidelines as:

“Two or more individual effects which, when considered together, are considerable or which compound or increase other environmental impacts.

- (a) The individual effects may be changes resulting from a single project or a number of separate projects.
- (b) The cumulative impact from several projects is the change in the environment which results from the incremental impact of the project when added to other closely related past, present, and reasonably foreseeable probable future projects. Cumulative impacts can result from individually minor but collectively significant projects taking place over a period of time (CEQA Guidelines Section 15355).”

According to the CEQA Guidelines, a Lead Agency must discuss the cumulative impacts of a project when the cumulative effect is significant and the project's incremental contribution to the cumulative effect would be “cumulatively considerable,” that is, when the incremental effects of a project would be significant when viewed in connection with the effects of past, present, and probable future projects (CEQA Guidelines Section 15065(a)(3); Section 15130(a)).

If the combined cumulative impact associated with the project's incremental effect and the effects of other projects would not be significant, an EIR should briefly indicate why the cumulative impact is not significant (CEQA Guidelines Section 15130(a)(2)).

Additionally, an EIR can determine that a project's contribution to a significant cumulative impact will be rendered less than cumulatively considerable and therefore not significant. A project's contribution can also be less than cumulatively considerable if the project is required to implement or fund its fair share of a mitigation measure or measures designed to alleviate the cumulative impact. The Lead Agency must identify facts supporting this conclusion (CEQA Guidelines Section 15130(a)(3)).

4.2 Cumulative Effects Methods

The Lead Agencies began analyzing cumulative effects in the Klamath Facilities Removal EIS/EIR by reviewing the impacts of the Proposed Action and alternatives on the specific environmental resources presented in Chapter 3. The Lead Agencies then identified past, present, and reasonably foreseeable future actions that could contribute to cumulative effects on each resource, and defined an area of analysis and timeframe for the potential cumulative effects for each resource. The Lead Agencies determined the significance of identified cumulative effects in accordance with CEQA requirements. As noted above, NEPA and CEQA have differing definitions of significance for cumulative effects; in most cases NEPA does not require a specific determination of significance, while CEQA does. If the Lead Agencies determined that a cumulative effect would be significant, feasible mitigation measures are proposed in this chapter. If no feasible mitigation would be possible (i.e., the technology does not exist), the cumulative effect is considered significant and unavoidable.

4.2.1 Identifying Past, Present, and Future Actions Contributing to Cumulative Effects

CEQA Section 15130(b)(1) identifies two methods that may be used to analyze cumulative impacts:

1. “A list of past, present, and probable future projects producing related or cumulative impacts, including, if necessary, those projects outside the control of the agency,” and/or
2. “A summary of projections contained in an adopted local, regional, or Statewide plan or related planning document, that describes or evaluates conditions contributing to the cumulative effect. Such plans may include: a general plan, regional transportation plan, or plans for the reduction of greenhouse gas emissions. A summary of projections may also be contained in an adopted or certified prior environmental document for such a plan. Such projections may be supplemented with additional information such as a

regional modeling program. Any such document shall be referenced and made available to the public at a location specified by the lead agency.”

The Lead Agencies analyzed cumulative impacts using both CEQA methods identified above. Some resources use a combination of both methods, when applicable. Table 4-1 lists the method used to evaluate the cumulative impacts for each resource, either the project method (#1) above, the projection method (#2) above, or a combination of both.

Table 4-1. Method for Developing the Cumulative Condition

Resource	Method for Developing the Cumulative Condition
Water Quality	(1) Project Method, and (2) Projection Method
Aquatic Resources	(1) Project Method, and (2) Projection Method
Algae	(1) Project Method, and (2) Projection Method
Terrestrial Resources	(1) Project Method
Flood Hydrology	(1) Project Method, and (2) Projection Method
Ground water	(1) Project Method, and (2) Projection Method
Water Supply/Water Rights	(1) Project Method
Air Quality	(1) Project Method, and (2) Projection Method
Greenhouse Gases/Global Climate Change	(2) Projection Method
Geology, Soils and Geologic Hazards	(1) Project Method
Tribal Trust	(1) Project Method
Cultural and Historic Resources	(1) Project Method
Land Use, Agricultural and Forest Resources	(1) Project Method
Socioeconomics	(1) Project Method, and (2) Projection Method
Environmental Justice	1) Project Method
Population and Housing	(2) Projection Method
Public Health and Safety, Utilities and Public Services, Solid Waste, Power	(1) Project Method, and (2) Projection Method
Scenic Quality	(2) Projection Method
Recreation	(1) Project Method
Toxic/Hazardous Materials	(1) Project Method
Traffic and Transportation	(1) Project Method
Noise and Vibration	(1) Project Method, and (2) Projection Method

The methods described above for CEQA are considered to be sufficient to identify past, present, and future actions for the NEPA cumulative analysis.

The Lead Agencies used a variety of Federal, tribal, State, county, and local government sources to identify and collect information on past, present, and reasonably foreseeable actions in the project area that could contribute to cumulative effects (see Table 4-2). These include:

- City and County General Plans
- Biological Management Plans
- Population, housing, traffic, and other projections found in existing city and county general plans
- Scoping comments
- Consultation with Federal and State agencies
- Published reports, documents, and plans
- Existing environmental documents

In addition to the documents reviewed above, the Lead Agencies mailed a formal request to the following transportation, city, and county planning departments on January 21, 2010, requesting information on past, present, and future actions in the area of analysis:

- Siskiyou County, California
- Klamath County, Oregon
- City of Yreka
- City of Chiloquin
- California Department of Transportation (Caltrans), District 2
- Oregon Department of Transportation, Region 4

Relevant information collected as part of this effort is presented Section 4.3 and was considered in this cumulative analysis.

4.2.2 Cumulative Effects Area of Analysis

Both NEPA and CEQA require a defined geographic scope for a cumulative effects analysis (Council of Environmental Quality [CEQ] 1997; CEQA Guidelines 15130(b)(3)). For NHPA, the Area of Potential Effects for the cumulative analysis is the same as the one defined in Section 3.13, Cultural and Historical Resources. The cumulative area of analysis for each resource in this EIS/EIR varies depending on the type of impacts that could occur and the nature of those impacts. The areas of analysis for some resource areas have clearly defined cumulative boundaries while others are more general in nature. Table 4-2 lists the area of analysis for each resource area's cumulative impacts related to the Klamath Hydroelectric Settlement Agreement (KHSA). The general cumulative effects area of analysis for the KBRA includes the Klamath Basin and its tributaries. Generally, fisheries programs proposed in the KBRA apply to

the entire basin, while programs related to water use apply mostly to the Upper Klamath Basin upstream of J.C. Boyle Dam. County and tribal programs apply to the relevant jurisdictions throughout the entire basin.

Table 4-2. Cumulative Effects Area of Analysis by Resource for Removal of the Four Facilities (KHSA)

Resource	Area of Analysis	Justification
Water Quality	Rivers, streams and reservoirs within the Upper and Lower Klamath Basins including Wood, Williamson and Sprague Rivers; Upper Klamath Lake; the Klamath River to the Klamath River Estuary; the Klamath River watershed; and the nearshore environment	This is the extent of physical and operational changes affecting water quality
Aquatic Resources	Surface waters within the Klamath Basin affected by dam removal activities excluding the Lost River watershed, Tule Lake basin, and Trinity River. The Klamath River to the Pacific Ocean and the nearshore environment	This is the extent of physical changes affecting water quality, habitat, and flows
Algae	Surface waters within the Klamath Basin affected by dam removal activities excluding the Lost River watershed, Tule Lake basin, and Trinity River. The Klamath River to the Pacific Ocean and the nearshore environment	This is the extent of physical changes affecting water quality, habitat, and flows
Terrestrial Resources	Klamath River channel and riparian habitat adjacent to the channel from Keno Dam downstream to the Pacific Ocean; the dam sites and construction areas, including equipment staging and access areas	This is the extent of physical changes affecting habitat
Flood Hydrology	The Klamath River watershed starting at J.C. Boyle reservoir and continuing downstream from the deconstruction area of the four dams to the Pacific Ocean	This is the extent of potential changes in surface water elevation
Ground water	Ground water supply wells adjacent to J.C. Boyle, Copco1, Copco 2, and Iron Gate reservoirs	This is the extent of physical changes affecting ground water
Water Supply/Water Rights	An area surrounding the Klamath River main stem between Upper Klamath Lake and Seiad Valley.	This is the extent of physical and operation changes affecting water supply and water rights
Air Quality	Klamath and Jackson Counties in Oregon and Siskiyou and Shasta Counties in California	Air quality impacts would occur within Siskiyou County, California and Klamath County, Oregon for Facility removal activities, while additional impacts could occur in Jackson County, Oregon and Shasta County, California from truck or construction worker travel
Greenhouse Gases/Global Climate Change	Greenhouse Gases geographic scope includes the entire State of California and Oregon	Total greenhouse gas emissions are available for the State of California; therefore this analysis examines cumulative greenhouse gas emission targets for the entire State

Table 4-2. Cumulative Effects Area of Analysis by Resource for Removal of the Four Facilities (KHSA)

Resource	Area of Analysis	Justification
Geology, Soils and Geologic Hazards	The reservoir bed and banks at the sites of the reservoirs impounded by J.C. Boyle Dam, Copco 1, Copco 2, and Iron Gate Dams, as well as the riverbed and adjacent banks along the Klamath River downstream from Iron Gate dam to its mouth at the Pacific Ocean	This is the extent of physical changes affecting geology, soils and geologic hazards
Tribal Trust	The area of analysis includes the entire 263 miles of the Klamath River and the Klamath Basin. The federally recognized tribes within this area of analysis include the Klamath Tribes, Quartz Valley Community, Karuk Tribe, Hoopa Valley Tribe, Yurok Tribe, and Resighini Rancheria	This is the geographic extent of the tribal trust resources that could be affected by the project are located
Cultural and Historic Resources	Known and unknown cultural and historic resources in the vicinity of the Four Facilities and the Klamath Basin where construction or land disturbance could occur	This is the extent of where cultural and historic resources could be affected
Land Use, Agricultural and Forest Resources	All lands directly adjacent to the Four Facilities	This is the extent of physical and operational changes affecting land use
Socioeconomics	Regional economies with Siskiyou, Humboldt, Del Norte, and Modoc counties in California and Klamath and Jackson counties in Oregon. For commercial fishing, regional economies also include San Mateo, San Francisco, Marin, Sonoma and Mendocino (as well as Humboldt and Del Norte) counties in California, and Curry, Coos, Douglas and Lane counties in Oregon.	This is the extent of the counties that could experience socioeconomic effects
Environmental Justice	Siskiyou, Humboldt, Del Norte, Shasta, Modoc and Mendocino counties in California and Klamath, Jackson and Curry counties in Oregon	These are the counties that contain environmental justice populations that could be affected by the project
Population and Housing	The area of analysis includes a combination of urban and rural communities: Hornbrook and Yreka in California and Klamath Falls and Medford in Oregon. The area of analysis also includes the residential rural areas immediately near the Copco 1 and 2 Dams and just upstream of the J. C. Boyle Dam	These are the communities with the potential to house temporary construction workers
Utilities and Public Services, Solid Waste, Public Health and Safety, Power	Utilities and Public Services: Existing utilities and public services supplying Siskiyou and Klamath Counties	These are the two counties that could experience utility and service effects from construction
	Solid Waste: Existing landfills in Siskiyou and Klamath Counties	Waste generated by the project would be sent to waste facilities in these two counties
	Public Health and Safety: The proposed dam deconstruction areas surrounding the Four Facilities (for deconstruction related safety issues), downstream from the dams (for flooding impacts), and the associated reservoirs (for impacts related to wildfires and public health issues)	This is the extent of construction activities that could affect public health and safety

Table 4-2. Cumulative Effects Area of Analysis by Resource for Removal of the Four Facilities (KHSA)

Resource	Area of Analysis	Justification
	Power: Existing generator facilities, employees and local customer base in Siskiyou and Klamath Counties and other potential power supply sources used to service the existing customer base	This is the extent of hydroelectric power service that would be affected by the Proposed Action. Other sources of power will be needed to replace lost service
Scenic Quality	All areas surrounding the Four Facilities that would have views of the four reservoirs or the Klamath River from J.C. Boyle to Iron Gate Dam	This is the extent of physical changes affecting aesthetics and visual resources
Recreation	Recreation areas at the lakes/reservoirs, the Klamath River and applicable tributaries within the Klamath Basin. Wildlife refuges and other regional recreation areas affected by changes at some reservoirs are included	This is the extent of physical and operational changes that could affect recreation
Toxic/Hazardous Materials	The proposed deconstruction areas surrounding the Four Facilities, transportation routes and disposal points for toxic hazardous materials	This is the area where exposure to toxic or hazardous materials could occur during deconstruction, transport and/or disposal activities
Traffic and Transportation	Roadways within Klamath and Jackson Counties in Oregon and within Siskiyou County in California	These are the roadways that would be used by construction vehicles and workers
Noise and Vibration	The region surrounding the Four Facilities and the haul routes in Klamath and Jackson Counties, Oregon and Siskiyou and Shasta Counties, California	This is the extent of where deconstruction and restoration activities would produce noise and vibration

4.2.3 Timeframe

Cumulative effects consider the timeframe for the project-specific analysis as well as how long the effects of the project are expected to last. There may be instances when the timeframe for cumulative effects must be expanded to encompass cumulative effects occurring further into the future (Council on Environmental Quality 1997). The Proposed Action and alternatives would not be implemented until 2020; however this cumulative analysis must rely on information available at the time of this document.

The timeframe for this cumulative effects analysis varies by environmental resource and is described for each resource area in this chapter. For several resources, impacts would occur only for the duration of deconstruction; for these resources, the cumulative effects analysis timeframe includes only the duration of deconstruction (May 2019 through December 2021). For other resources, long-term effects could occur even after deconstruction, so the Lead Agencies examined a longer timeframe. The timeframe for cumulative effects analysis also depends on the type of information available. Many general plans or other documents that are used to obtain relevant projections only have forecasts for 10 or 20 years from the date of the document. The timelines identified for long-term cumulative effects are based on the best available existing information. The cumulative effects analysis also accounts for past and present projects to the extent feasible.

4.2.4 Mitigation

4.2.4.1 National Environmental Policy Act

According to NEPA, a discussion on mitigation for adverse environmental effects is required in an EIS (40 Section Part 1502.16(h), 40 CFR Section 1502.14(f)); however, a final set of mitigation measures that are selected for implementation are adopted in a Record of Decision (ROD). If mitigation measures presented in the EIS are not adopted, the reasons why must be explained in the ROD (40 CFR Section 1505.2(c)). This cumulative effects analysis will identify potential mitigation for significant cumulative effects; the ROD will present the final mitigation measures adopted as part of the project that will be completed with the respective alternative selected for implementation.

4.2.4.2 National Historic Preservation Act

The United States Department of the Interior (DOI) is required to develop appropriate measures to avoid, minimize, or mitigate adverse effects to historic properties under Section 106 of the NHPA (36 CFR Sections 800.6, 800.8(c)(1)(v)). Such measures were identified and described in Chapter 3.13. These measures will be incorporated into the ROD and will become binding terms for addressing potential adverse effects to historic properties, including such effects identified as cumulative.

4.2.4.3 California Environmental Quality Act

Mitigation requirements of CEQA differ from those of NEPA. An EIR must examine reasonable, feasible options for mitigating or avoiding the project's contribution to any significant cumulative effects (CEQA Guidelines Section 15130). In addition, no public agency can approve or carry out a project with an EIR that identifies significant impacts unless the public agency makes one or more written findings for each of those significant effects (CEQA Guidelines Section 15091). Therefore, CEQA requires each public agency to mitigate or avoid the significant effects of projects that it carries out or approves whenever it is feasible to do so. (Pub. Res. Code § 21002.1(b)). This cumulative effects analysis will identify all feasible mitigation measures for effects of the project determined to be “cumulatively considerable.” The certification of the EIR and subsequent CEQA findings will contain the feasible mitigation measures adopted as part of the project.

4.3 Actions and Projects Considered in Cumulative Effects Analysis

This section outlines all the past, present, and reasonably foreseeable actions or projects that could contribute to cumulative effects and that were considered in the analysis.

4.3.1 Documents Reviewed

The Lead Agencies consulted many documents as part of this cumulative effects analysis to identify projects, plans, programs, and projections. Table 4-3 lists the documents considered in this analysis.

Table 4-3. Plans, Programs, and Other Documents Considered in Cumulative Effects Analysis

Author	Document Title	Coverage Area	Resource Topic(s) Addressed	Date Published	Timeframe Covered
Federal					
Reclamation, U.S. Fish and Wildlife Service, Hoopa Valley Tribe, and Trinity County	Trinity River Mainstem Fishery Restoration Final Environmental Impact Statement and Record of Decision	Trinity River	Aquatic Resources	2000	Undefined
U.S. Environmental Protection Agency	Trinity River Total Maximum Daily Load for Sediment	Trinity River	Aquatic Resources, Water Quality	2001	Undefined
Department of the Interior	Long Range Plan for the Klamath Basin Conservation Area Fishery Restoration Program (Klamath River Basin Fisheries Task Force 1991)	Klamath Basin	Aquatic Resources, Water Quality	1991	1986 to 2006
National Oceanic and Atmospheric Administration Fisheries Service	Final Environmental Assessment: Authorization for Incidental Take and Implementation of the PacifiCorp Klamath Hydroelectric Project Interim Operations Habitat Conservation Plan for coho Salmon	PacifiCorp's existing Project facilities and the adjacent water and land areas potentially influenced by Project maintenance and operations, including the mainstem Klamath River and reservoirs from Link River dam at the outlet of Upper Klamath Lake down to the Klamath River estuary	Aquatic Resources	2012	10 years
National Oceanic and Atmospheric Administration Fisheries Service Southwest Region	Biological Opinion for Klamath River Project - Operation of the Klamath Project between 2010 and 2018 and its Effects on South Oregon/Northern California Coast coho Salmon	Klamath Project Area - Klamath County, Oregon, Siskiyou and Modoc Counties, California	Aquatic Resources	2010	2010 to 2018
National Oceanic and Atmospheric Administration Fisheries Service	Draft Central California Coast coho Salmon Recovery Plan	West Coast from British Columbia to California	Aquatic Resources	2010	Undefined
National Oceanic and Atmospheric Administration Fisheries Service	Critical Habitat for the Southern Distinct Population Segment of Eulachon	California	Aquatic Resources	2010	Undefined

Table 4-3. Plans, Programs, and Other Documents Considered in Cumulative Effects Analysis

Author	Document Title	Coverage Area	Resource Topic(s) Addressed	Date Published	Timeframe Covered
National Oceanic and Atmospheric Administration Fisheries Service and United States Fish and Wildlife Service	Draft Environmental Impact Statement for Authorization for Incidental Take and Implementation of Fruit Growers Supply Company's Multispecies Habitat Conservation Plan	The Klamath River and Scott Valley management units are located west of Interstate 5, adjacent to and intermixed with Klamath National Forest lands	Aquatic Resources, Terrestrial Resources	2009	50 Years
National Oceanic and Atmospheric Administration Fisheries Service	2007 Federal Recovery Outline Southern Oregon/Northern California Coast coho Salmon	California and Oregon	Aquatic Resources	2007	Undefined

¹ If a new license is issued by the Federal Energy Regulatory Commission for the Klamath Hydroelectric Project, the Project would need to comply with the recommendations set forth in this Biological Opinion. Because the existing license expired in 2006, the Klamath Hydroelectric Project is currently operating under an annual license with the same terms and conditions of the prior, existing license.

² If a new license is issued by the Federal Energy Regulatory Commission for the Klamath Hydroelectric Project, the Project would need to comply with the recommendations set forth in this Biological Opinion. Because the existing license expired in 2006, the Klamath Hydroelectric Project is currently operating under an annual license with the same terms and conditions of the prior, expired license.

4.3.2 Cumulative Projects

The Lead Agencies reviewed past, present, and future projects in the geographically defined area as part of this cumulative effects analysis. Table 4-4 lists the projects considered in this analysis.

4.4 Cumulative Effects Analysis

This section describes, by resource, the cumulative effects of the KHSA and KBRA. For each resource category, the analysis is structured as follows:

- A summary of each resource’s impacts and mitigation measures presented in Chapter 3;
- A discussion of potential cumulative effects utilizing either the project method, the projection method, or a combination of both (as described in Section 4.2.1);
- A discussion of the incremental contribution of the alternative to the cumulative effect and whether that contribution is cumulatively considerable; and
- A discussion of any mitigation measures.

With regard to the summary table of impacts specific to each resource, the delineation of applicable alternatives and conclusions of significance are abbreviated as follows:

Alternatives

- 1 = No Action/No Project
- 2 = Full Facilities Removal of Four Dams Alternative (Proposed Action)
- 3 = Partial Facilities Removal of Four Dams Alternative
- 4 = Fish Passage at Four Dams Alternative
- 5 = Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative

Significance

- NCFEC = No Change From Existing Conditions
- B = Beneficial
- LTS = Less than Significant
- S = Significant

This cumulative analysis considers adverse effects of the project identified in Chapter 3 that are less than significant or significant. It also considers beneficial effects. If an impact has been determined to have no effect, then it would not contribute to any cumulative effects and it is not discussed in this section. This cumulative analysis does not evaluate the No Action/No Project Alternative because it already includes reasonably foreseeable past, present, and future projects.

Three resource categories, Environmental Justice, Socioeconomics, and Tribal Trust are NEPA requirements and are analyzed according to NEPA; therefore they do not require a specific determination of significance. The cumulative effects analysis for each of these resource categories describes potential cumulative effects but does not make a determination of whether or not they would be cumulatively considerable or significant (i.e., for all other resource categories, CEQA conclusions, shown in bold type, are presented at the end of each impact discussion).

The KBRA is analyzed at a programmatic level of detail in this cumulative effects analysis because the specific locations, timeframes, and construction methods for KBRA actions are not yet known. Where adequate information on KBRA actions is available, general cumulative effects are discussed. Where information is not sufficient for a detailed cumulative effects analysis, or there is a high level of uncertainty as to what actions would occur and how they would affect resources, this is noted in the text and no attempt at speculation is made. As noted throughout this document, future environmental analysis will be completed as necessary.

4.4.1 Water Quality

Cumulative effects on water quality could be caused by short-term and long-term water quality impacts of the project, combined with other projects/actions in the Klamath Basin that could contribute to adverse water quality effects. The timeframe for short-term water quality effects related to reservoir drawdown is up to 2 years after reservoir drawdown begins, although modeling suggests most water quality effects would be negligible after a year (see Section 3.2.4.3, Water Quality). The timeframe for long-term cumulative water quality effects extends from 2 to 50 years, which includes the remainder of the Project analysis period and applies for the majority of the available numeric models of future water quality in the Klamath River.

The water quality modeling performed for the impact analysis in Chapter 3 already considers some cumulative actions such as implementation of the Total Maximum Daily Loads (TMDLs) in order to forecast future water conditions at the time the Proposed Action and alternatives would be implemented. This cumulative effects analysis focuses on additional projects not already considered in the water quality modeling.

Table 4-5 presents a summary of the water quality impacts identified in Chapter 3. These impacts are analyzed for cumulative effects below the table.

Table 4-5. Summary of Water Quality Impacts from Chapter 3

Potential Impact	Alternatives	Significance	Mitigation	Significance after Mitigation
Water Temperature				
Upper Klamath Basin				
Continued impoundment of water in the reservoirs could cause short-term and long-term seasonal water temperatures that are shifted from the natural thermal regime of the river and do not meet applicable Oregon DEQ and California Basin Plan water quality objectives and adversely affect beneficial uses in the Hydroelectric Reach.	1	NCFEC	<i>None</i>	NCFEC
Dam removal and/or reduction or elimination of hydropower peaking operations at J.C. Boyle Powerhouse could cause short-term and long-term alterations in daily water temperatures and diel temperature variation in the J.C. Boyle bypass and peaking reaches.	2, 3, 4, 5	LTS for J.C. Boyle Bypass Reach in summer/fall B for J.C. Boyle Peaking Reach in summer/fall	<i>None</i>	LTS for J.C. Boyle Bypass Reach in summer/fall B for J.C. Boyle Peaking Reach in summer/fall
Dam removal and conversion of the reservoir areas to a free-flowing river could cause short-term and long-term increases in spring time water temperatures and decreases in late summer/fall water temperatures in the Hydroelectric Reach downstream from Copco 1 Reservoir.	2, 3, 5	LTS for springtime B for late summer/fall	<i>None</i>	LTS for springtime B for late summer/fall
Lower Klamath Basin				
Draining the reservoirs and release of sediment could cause short-term and long-term increases in sediment deposition in the Klamath River or Estuary that could alter morphological characteristics and indirectly affect seasonal water temperatures.	2, 3, 5	NCFEC	None	NCFEC
Continued impoundment of water in the reservoirs could cause short-term and long-term seasonal water temperatures that are shifted from the natural thermal regime of the river and do not meet applicable California North Coast Basin Plan water quality objectives and adversely affect beneficial uses in the Klamath River downstream from Iron Gate Dam.	1, 4	NCFEC	None	NCFEC

Water quality in multiple locations in the Klamath River is characterized by seasonally high concentrations of algal-derived (organic) suspended material, high water temperatures, low dissolved oxygen, and high pH levels (North Coast Regional Water Quality Control Board [NCRWQCB] 2010a). A lack of carbonate rock sources in the basin results in generally low alkalinity waters and during the daytime when photosynthesis is occurring, high pH levels can exceed Oregon, California, and Hoopa Valley Tribe water quality objectives (see Section 3.2.3, Water Quality). The export of nutrients and organic matter from Upper Klamath Lake has contributed to water quality issues in the downstream Klamath River, including high levels of biological productivity and respiration (NCRWQCB 2010a). The stable lacustrine environment created at the Four Facilities, particularly in the larger Copco 1 and Iron Gate Reservoirs, coupled with high nutrient availability and high water temperatures in summer to fall, provides ideal conditions for phytoplankton growth. Within the Klamath Basin, blue-green algal productivity is locally and seasonally associated with extreme daily fluctuations in DO levels (high during the day and low at night), and elevated pH and free ammonia concentrations, which do not meet Oregon water quality standards during the summer months (See Section 3.2.2.3). Nuisance algal blooms that occur in the Klamath Basin are primarily composed of three species of blue-green algae: *Aphanizomenon flos-aquae*, *Anabaena flos-aquae*, and *M. aeruginosa*. Large blooms of *Aphanizomenon flos-aquae* and *Anabaena flos-aquae* can strongly influence pH, free ammonia, and DO concentrations.

Many past and present cumulative actions and projects have contributed to the Klamath River's adverse water quality conditions, including the establishment and operation of the Klamath Hydroelectric Project (KHP) and Reclamation's Klamath Project, large-scale conversion of wetlands in the Upper Klamath Basin to irrigated agricultural lands, grazing, road construction and related run-off, timber harvesting, mining, water diversions, and development (see also Section 3.2.3.1, Water Quality).

Future actions that could cumulatively affect water quality in the Klamath Basin include proposed new subdivisions and road improvements in or near the Klamath River. There are also many ongoing restoration actions and projects in the Klamath Basin (identified in Tables 4-3 and 4-4) that have or will contribute to future water quality improvements in the Klamath River.

4.4.1.1 Alternative 2: Full Facilities Removal of Four Dams

4.4.1.1.1 Temperature

Removal of the Four Facilities under the Proposed Action and elimination of hydropower peaking operations at J.C. Boyle Powerhouse could result in short-term (<2 years following dam removal) and long-term (2–50 years following dam removal) alterations in overall water temperatures and diel water temperature fluctuations in the J.C. Boyle Bypass and Peaking Reaches. Klamath TMDL model results indicate that under the Proposed Action, water temperatures in the Bypass Reach immediately downstream from J.C. Boyle Dam would be similar to those under the No Action/No Project Alternative, but there would be relatively greater diel water temperature variation during June through September due to the absence of the thermal mass in J.C. Boyle Reservoir. Greater diel variation would also occur further downstream in the J.C. Boyle Bypass Reach. The anticipated increases in summer/fall water temperatures and daily diel temperature variation in the J.C. Boyle Bypass Reach due to the removal of J.C. Boyle Reservoir and elimination of bypass hydropower peaking operations would be a less than significant impact.

In the J.C. Boyle Peaking Reach model results indicate that water temperatures under the Proposed Action would exhibit slightly lower daily maximum values (0.0–2 °C [0–3.6 °F]) as compared to those predicted under the No Action/No Project Alternative and would exhibit *lower* diel water temperature variation during June through September. The anticipated slight decreases in long-term maximum summer/fall water temperatures and less artificial water temperature swings in the J.C. Boyle Peaking Reach would be beneficial.

In the J.C. Boyle Bypass Reach, the Proposed Action's contribution to this cumulative effect would not be cumulatively considerable for the area directly downstream from J.C. Boyle Dam. Water temperatures in this short river reach (i.e., downstream from the cold springs) would increase during summer months due to the elimination of bypass operations; however, areas adjacent to the coldwater springs in the Bypass Reach would continue to serve as thermal refugia for aquatic species because the springs themselves would not be affected by the Proposed Action. Further, a shift in water temperatures toward natural diel variation would increase daily maximum temperatures, but would also

increase nighttime minimum water temperatures providing regular thermal relief, time for repair of proteins damaged by thermal stress, and significant bioenergetic benefits for salmonids.

In the J.C. Boyle Peaking Reach, temperature changes would be cumulatively beneficial. In the J.C. Boyle Peaking Reach model results indicate that water temperatures under the Proposed Action would exhibit slightly lower daily maximum values as compared to those predicted under the No Action/No Project and would exhibit *lower* diel water temperature variation during June through September, moving toward the natural thermal regime (Figure 3.2-3) (NCRWQCB 2010a, data from electronic appendices of Asarian and Kann 2006b). At these locations the relative difference in diel water temperature variation between the Proposed Action and the No Action/No Project Alternative is due to the elimination of peaking operations and the associated large artificial temperature swings. Overall, the TMDL model results indicate that June through October riverine water temperatures from J.C. Boyle Reservoir to the Oregon-California State line would meet the Oregon narrative natural conditions criterion that supersedes the numeric objective (i.e., 20°C [68°F], see Table 3.2-3) for support of coolwater habitat.

The Proposed Action’s incremental contribution to the short-term and long-term cumulative effects on summer/fall water temperatures and diel temperature variation in the J.C. Boyle Bypass Reach would not be cumulatively considerable. The Proposed Action’s incremental contribution to the significant cumulative effects associated with decreases in long-term maximum summer/fall water temperatures and less artificial water temperature swings in the J.C. Boyle Peaking Reach would be beneficial.

Removal of the Four Facilities under the Proposed Action and conversion of the reservoir areas to a free-flowing river could result in short-term (<2 years following dam removal) and long-term (2–50 years following dam removal) increases in spring water temperatures and decreases in late summer/fall water temperatures and increase diel temperature variation in the Hydroelectric Reach downstream from Copco 1 Reservoir and in the Lower Klamath River. In the California portion of the Hydroelectric Reach, removal of the Four Facilities under the Proposed Action would eliminate the seasonal temperature shift caused by the Four Facilities in the Hydroelectric Reach such that spring water temperatures would increase and late summer/fall temperatures would decrease. Additionally, the Proposed Action could result in short-term and long-term increases in spring water temperatures, decreases in late summer/fall water temperatures, and increased diel temperature variation in the Lower Klamath River.

Water temperatures in the Klamath Hydroelectric Reach are influenced by the presence of the Four Facilities. As noted in Section 3.2, Water Quality, the large thermal mass of the stored water in the reservoirs delays the natural warming and cooling of riverine water temperatures on a seasonal basis such that spring water temperatures in the Klamath Hydroelectric Reach are generally cooler than would be expected under natural conditions, and summer and fall water temperatures are generally warmer (NCRWQCB 2010a). The temporal water temperature pattern of the Hydroelectric Reach is repeated

in the Klamath River immediately downstream from Iron Gate Dam, where water released from the reservoirs is 1–2.5°C (1.8–4.5°F) cooler in the spring and 2–10°C (3.6–18°F) warmer in the summer and fall as compared to modeled conditions without the dams (PacifiCorp 2004a, Dunsmoor and Huntington 2006, NCRWQCB 2010a). Immediately downstream from Iron Gate Dam (RM 190.1), water temperatures are also less variable than those documented farther downstream in the Klamath River (Karuk Tribe of California 2009, 2010).

Farther downstream, the presence of the Four Facilities exerts less influence and water temperatures are more influenced by the natural heating and cooling regime of ambient air temperatures and tributary inputs of surface water. Meteorological control of water temperatures result in increasing temperature with distance downstream from Iron Gate Dam. By the Salmon River (RM 66), the effects of the dams on water temperature are not discernable.

Besides the influence of the reservoirs, the other major factor that could contribute to cumulative effects on water quality is climate change. Climate change is expected to increase summer and fall water temperatures in the Klamath Basin on the order of 1–3°C (1.8–5.4°F) (Bartholow 2005, Perry et al. 2011). The Upper Klamath River from the Oregon-California State line to Iron Gate Dam, the Middle Klamath River from Iron Gate Dam to Scott River, and the Lower Klamath River from Scott River to the mouth are all listed as impaired for water temperature according to the CWA Section 303d list. Water temperature is therefore a significant cumulative effect for the Klamath River in the Hydroelectric Reach downstream from Copco 1 Reservoir and the Lower Klamath River.

The Proposed Action's incremental contribution to the short-term and long-term cumulative effects on water temperatures would not be cumulatively considerable for spring water temperatures in the Hydroelectric Reach from Copco 1 Reservoir to Iron Gate Reservoir in May and June. Cooler fall water temperatures would likely lead to earlier fall-run Chinook spawning in the mainstem (reducing pre-spawn mortality) and a temperature regime more in sync with historical spawning timing. Earlier spawning and warmer spring temperatures would likely result in fry emerging earlier and growing faster, which could encourage earlier emigration downstream, reducing stress and disease (Bartholow 2005, FERC 2007). Diel temperature variations in the Hydroelectric Reach would not be cumulatively considerable. Downstream from Copco 1 and Copco 2 Reservoirs (≈RM 198), the Proposed Action would increase daily maximum temperatures that are currently up to 7 °C (13 °F) lower than modeled natural conditions in spring (May and June) and would decrease temperatures that are up to roughly 4°C (7°F) greater than modeled natural

conditions in late summer/fall (August through October), due to the presence of the reservoirs. However, the Proposed Action would also decrease temperatures in this same reach in August and October, contributing to cumulative beneficial effects.

In the Lower Klamath River, the Proposed Action's incremental contribution to the cumulative effects on spring water temperatures and diel temperature variations would

not be cumulatively considerable, as discussed above. The Proposed Action's contribution to the cumulative effects on temperature would be beneficial in late summer/fall by resulting in cooler water temperatures. These impacts would decrease in magnitude with distance downstream from Iron Gate Dam, and would not be expected to result in temperature changes in the lower river downstream from the confluence with the Salmon River, including the Klamath Estuary and the marine nearshore environment.

The Proposed Action's incremental contribution to the short-term (<2 years following dam removal) and long-term (2-50 years following dam removal) cumulative effects on increased spring water temperatures and diel water temperature variations would not be cumulatively considerable for the Hydroelectric Reach and the Lower Klamath River to the confluence with the Salmon River. The Proposed Action's incremental contribution to the cumulative effects on water temperatures would be beneficial in the fall in the Hydroelectric Reach and the Lower Klamath River to the confluence with the Salmon River.

4.4.1.1.2 Suspended Sediments

Suspended sediment release associated with the Proposed Action could cause short-term (<2 years following dam removal) increases in suspended material in the Hydroelectric Reach downstream from J.C. Boyle Dam, the Lower Klamath River and the Klamath Estuary due to the release of sediments currently trapped behind the dams at the Four Facilities. Sediment release associated with the removal of the Four Facilities under the Proposed Action could cause short-term increases in sediment loads from the Klamath River to the Pacific Ocean and corresponding increases in concentrations of suspended material in the marine nearshore environment. Stormwater runoff from deconstruction activities under the Proposed Action could cause short-term increases in suspended material in the Hydroelectric Reach during the deconstruction period. Interim Measures (IMs) would cause short-term increases in suspended sediment associated with construction activities. Construction of the Yreka Water Supply Pipeline under the Proposed Action could cause short-term increases in suspended material in the Hydroelectric Reach during the construction period. Under the Proposed Action, recreational facilities currently located on the banks of the existing reservoirs will be removed following drawdown, and could release suspended sediment into the Klamath River. Under the Proposed Action, revegetation associated with management of the reservoir footprint area could decrease the erosion of fine sediments from exposed reservoir terraces in the Hydroelectric Reach. The Proposed Action would increase short-term suspended sediment concentrations through the release of sediment trapped behind the dams. Within the general uncertainty of the model predictions, suspended sediment concentrations (SSCs) at J.C. Boyle Reservoir across the three water year types would have peak values of 2,000–3,000 mg/L and occurring within 1–2 months of reservoir drawdown. Predicted SSCs quickly decrease to less than 100 mg/L for 5–7 months following drawdown, and concentrations less than 10 mg/L for 6–10 months following drawdown.

Sediment transport modeling of the impacts of dam removal on suspended sediment in the Lower Klamath River indicates high short-term loads immediately downstream from Iron Gate Dam under the Proposed Action (Reclamation 2012, Stillwater Sciences 2008).

Overall, and within the general uncertainty of the model predictions, SSCs across the three water year types would have peak values of 7,000–14,000 mg/L and would occur within 2–3 months of reservoir drawdown. SSCs in excess of 1,000 mg/L would occur on a timescale of weeks to months, as compared to SSCs greater than 1,000 mg/L that can occur during winter storm events on a timescale of days to weeks under existing conditions in the Klamath River downstream from Iron Gate Dam. Predicted SSCs would remain greater than or equal to 100 mg/L for 5–7 months following drawdown, and concentrations would remain greater than or equal to 30 mg/L for 6–10 months following drawdown. Model results also indicate that while dilution in the lower river would decrease SSCs to 60–70 percent of their initial value downstream from Seiad Valley and to 40 percent of their initial value downstream from Orleans, within a factor of 2 uncertainty for the model results it can be conservatively assumed that SSCs in the Lower Klamath River would be sufficient (≥ 30 mg/L) to substantially adversely affect beneficial uses throughout the lower River and the Klamath Estuary for 6–10 months following drawdown (Reclamation 2012).

The results of model predictions for sediment transport following dam removal under the Proposed Action indicate that dam removal would cause a release of less than 3 million tons of fine sediment to the Lower Klamath River downstream from Iron Gate Dam. While estimates of long-term average annual sediment discharge to the Klamath Estuary vary considerably, they are generally well above the projected 3 million tons. Due to the relatively small magnitude of SSCs released to the nearshore environment, the anticipated rapid dilution of the sediment plume as it expands in the ocean, and the relatively short duration of high SSCs, the short-term increases in SSCs in the marine nearshore environment under the Proposed Action would not be substantial.

Stormwater runoff from deconstruction activities, relocation of recreation facilities, implementation of Interim Measures 7 and 16, and the relocation of the Yreka pipeline could also contribute to erosion and runoff of sediments into the waterway. However, the potential for sediments to enter the water from deconstruction site runoff or in-water deconstruction work could be minimized or eliminated through the implementation of Best Management Practices (BMPs) for deconstruction activities that would occur in or adjacent to the Klamath River. Establishment of herbaceous vegetation in drained reservoir areas would be undertaken to stabilize the surface of the sediment and minimize erosion from exposed terrace surfaces following drawdown.

Several of the cumulative actions and projects identified in Table 4-4 above have the potential to increase erosion and the release of sediment into the Klamath River, including the transportation improvement project in Siskiyou County, construction of approved new subdivisions in Siskiyou County, and any other proposed developments that could involve ground disturbance. Other more general projects and activities that are not easily identifiable but likely to occur, such as timber harvesting, mining, and agriculture, livestock grazing, and road-related erosion, could also contribute to cumulative effects associated with suspended sediment. Climate change could also affect suspended sediment by increasing the number of heavy precipitation events each year.

As described in Section 3.10, Greenhouse Gases/Global Climate Change, increases in heavy precipitation may result in a variety of general consequences for the Pacific Northwest:

- Increased fine sediment in streams may result in negative effects on the spawning of native fish that build their nests in the areas of clean rocks and gravel (Barr et al. 2010).
- Increased frequency and severity of flooding may occur.
- Increased runoff may lead to surface water quality changes including increased turbidity, increased organic content, color changes, and alkalinity changes.

The Lower Klamath River from the Trinity River to the mouth is listed as impaired under CWA Section 303(d) for sedimentation/siltation impairment. Suspended sediment is therefore a significant cumulative effect.

The Proposed Action's contribution to the cumulative effects associated with suspended sediment would be short term but would remain high for several months after reservoir drawdown in the Hydroelectric Reach, the Lower Klamath River, and in the Klamath Estuary and would exceed water quality objectives. **Therefore, the Proposed Action's incremental contribution to the short-term significant cumulative effects associated with suspended sediment concentrations during reservoir drawdown and dam deconstruction would be cumulatively considerable for the Hydroelectric Reach, Lower Klamath River, and the Klamath Estuary. No feasible mitigation is available to reduce these impacts; therefore they remain cumulatively considerable.**

Under the Proposed Action, the lack of continued interception and retention of mineral (inorganic) and algal-derived (organic) suspended material by the dams at the Four Facilities could result in long-term (2–50 years following dam removal) increases in suspended material in the Hydroelectric Reach, Lower Klamath River, Klamath Estuary, and marine nearshore environment. As noted above, short-term sediment release results in a significant cumulative water quality effect for the Klamath River. The Proposed Action's contribution to the long-term cumulative effects associated with lack of continued interception and retention of inorganic and organic material would be minor. Peak concentrations of mineral (inorganic) suspended material in the Hydroelectric Reach and Lower Klamath Basin during the winter/early spring (November through April) would likely remain associated with high-flow events and any increases due to the lack of interception by the dams would not be large.

Episodic increases (10–20 mg/L) in algal-derived (organic) suspended material resulting from in-reservoir algal productivity are not expected to occur in the Hydroelectric Reach following dam removal. SSCs in the Hydroelectric Reach may attain levels similar to those observed upstream of J.C. Boyle Dam under existing conditions during May through October (>15 mg/L; see Appendix C), as algal-dominated suspended material is transported downstream from Upper Klamath Lake. If slight long-term increases in suspended materials did occur, they would likely be offset by the loss of algal-derived suspended material previously produced in Copco 1 and Iron Gate Reservoirs and would

not exceed levels that would substantially adversely affect the cold freshwater habitat (COLD) beneficial uses. **Therefore, the Proposed Action's incremental contribution to the long-term significant cumulative effects associated with suspended material would not be cumulatively considerable.**

4.4.1.1.3 Nutrients

Sediment release associated with the removal of the Four Facilities under the Proposed Action could cause short-term (<2 years following dam removal) increases in sediment-associated nutrients. Short-term increases in total nitrogen (TN) and total phosphorus (TP) concentrations in the Lower Klamath River would occur because particulate (primarily organic) nutrients contained in reservoir sediment deposits would be transported along with the sediments themselves.

While no specific projects, including the projects reviewed for purposes of this analysis of cumulative effects, have been identified that would increase nutrient levels during reservoir drawdown, general activities that are not easily identifiable but likely to occur, such as grazing and agriculture, could contribute to this cumulative effect. The entire middle and lower reaches of the Klamath River, beginning at State line (RM 208.7) and moving downstream, are currently listed as impaired under California's Section 303(d) list for nutrients (State Water Resources Control Board [SWRCB] 2010). Therefore nutrients represent a significant cumulative water quality effect.

The Proposed Action's contribution to the cumulative effect would minimal. Minimal deposition of fine suspended sediments, including associated nutrients, would occur in the river channel (Reclamation 2012, Stillwater Sciences 2008). Further, reservoir drawdown under the Proposed Action would occur during winter months when rates of primary productivity and microbially mediated nutrient cycling (e.g., nitrification, denitrification) are also expected to be low. Light limitation for primary producers that do persist during winter months is also likely to occur, further decreasing the potential for uptake of TN and TP released along with reservoir sediment deposits. Therefore, particulate nutrients released along with sediment deposits are not expected to be bioavailable and should be well-conserved during transport through the Hydroelectric Reach. **The Proposed Action's incremental contribution to the short-term significant cumulative effects associated with increases in nutrients would not be cumulatively considerable.**

Removal of the Four Facilities under the Proposed Action and conversion of the reservoir areas to a free-flowing river could cause long-term (2–50 years following dam removal) increases in nutrient levels. Under the Proposed Action, nutrients otherwise trapped by the dams would be transported downstream and potentially be available for uptake (e.g., by nuisance algae species).

Primary nutrients including nitrogen and phosphorus are affected by the geology of the surrounding watershed of the Klamath River, upland productivity and land uses, as well as a number of physical processes affecting aquatic productivity within reservoir and riverine reaches. The relatively low relief, volcanic terrain of the Upper Klamath Basin

supports large, shallow natural lakes (Upper Klamath Lake, Agency Lake, Tule Lake, Lower Klamath Lake) and wetlands, with soils that are naturally high in phosphorus. Human activities in the Upper Klamath Basin, including wetland draining, agriculture, ranching, timber harvesting, and water diversions have increased concentrations of nutrients (nitrogen and phosphorus) in waterways.

Nitrogen arriving in Upper Klamath Lake has been attributed to upland soil erosion, runoff and irrigation return flows from agriculture, as well as *in situ* nitrogen fixation by cyanobacteria (Oregon Department of Environmental Quality [ODEQ] 2002). Although the relatively high levels of phosphorus present in the Upper Klamath Basin's volcanic rocks and soils have been identified as a major contributing factor to phosphorus loading to the lake (ODEQ 2002), land use activities in the Upper Klamath Basin have also been linked to increased nutrient loading, subsequent changes in its trophic status, and associated degradation of water quality. Extensive monitoring and research has been conducted for development of the Upper Klamath Lake TMDLs (ODEQ 2002) that shows the lake is a major source of nitrogen and phosphorus loading to the Klamath River.

While no specific cumulative projects have been identified that would increase nutrient levels, general activities that are not easily identifiable but likely to occur, such as timber harvesting, grazing, and other agricultural activities, could contribute to this cumulative effect. The entire middle and lower reaches of the Klamath River, beginning at State line RM 208.7) and moving downstream, are currently listed as impaired under California's Section 303(d) list for nutrients (SWRCB 2010a). Therefore nutrients represent a significant cumulative water quality effect for the Klamath River. The implementation Klamath Basin TMDLs for nutrients would help to reduce nutrient levels over time, but for the purposes of analysis this remains a significant cumulative effect.

The Proposed Action's contribution to the cumulative effect would minimal. Modeling conducted for development of the California Klamath River TMDLs (NCRWQCB 2010a) indicates that under the Proposed Action (similar to the TMDL TOD2RN scenario, which includes Oregon TMDL allocations), TP and TN in the Hydroelectric Reach immediately downstream from J.C. Boyle Dam would increase slightly (<0.015 mg/L and <0.05 mg/L, respectively) during summer months compared to those of the No Action/No Project Alternative (similar to the TMDL T4BSRN scenario) due to the absence of nutrient interception and retention in both Keno Impoundment/Lake Ewauna and J.C. Boyle Reservoir (the former because the TMDL model TOD2RN scenario includes the historic Keno Reef instead of Keno Dam [Appendix D]). At the Oregon-California State line, the situation would be much the same, although the lack of hydropower peaking operations under the Proposed Action may result in decreased daily variation in TP and ortho-phosphorus, as well as nitrate and ammonium (NCRWQCB 2010a). Concentrations of both nutrients are high enough in the river from Iron Gate Dam (RM 190.1) to approximately Seiad Valley (RM 129.4) (and potentially further downstream) that nutrients are not likely to be limiting primary productivity (i.e., periphyton growth) in this portion of the Klamath River (FERC 2007, HVTEPA 2008, Asarian et al. 2010). Overall, the increases would not be expected to

result in exceedances of either Oregon water quality objectives for nuisance algae growth, or California North Coast Basin Plan water quality objectives for biostimulatory substances, beyond levels experienced under the No Action/No Project Alternative. Further, the lacustrine environment that supports the growth of nuisance algae blooms of such as *M. aeruginosa* or other cyanobacteria would be eliminated under the Proposed Action (see Section 3.4, Algae), reducing the likelihood of uptake of the slightly increased nutrient concentrations by nuisance algae species. This is mainly relevant for Copco 1 and Iron Gate Reservoirs, where the longer residence times support seasonal nuisance algae blooms (see Section 3.4, Algae). Modeling results indicate small increases in TP and relatively larger increases in TN concentrations downstream from the Hydroelectric Reach under the Proposed Action, which diminish with distance downstream due to both tributary dilution and nutrient retention (i.e., uptake of nutrients). **The Proposed Action's incremental contribution to the significant cumulative effect associated long-term increases in nutrients in the Lower Klamath River and the Klamath River Estuary after dam removal would not be cumulatively considerable.**

4.4.1.1.4 Dissolved Oxygen

Sediment release associated with the Proposed Action could cause short-term (<2 years following dam removal) increases in oxygen demand (Immediate Oxygen Demand [IOD] and Biological Oxygen Demand [BOD]) and reductions in dissolved oxygen in the Hydroelectric Reach downstream from J.C. Boyle Reservoir, the Lower Klamath River, the Klamath Estuary, and the marine nearshore environment. Under the Proposed Action, high SSCs are expected in the middle and Lower Klamath River immediately following dam removal. The high fraction of organic carbon present in the reservoir sediments (see Section 3.2.3.1, Water Quality) allows for the possibility of oxygen demand generated by microbial oxidation of organic matter exposed to the water column from deep within the sediment profile and mobilized during dam removal.

The entire middle and lower reaches of the Klamath River, beginning at State line (RM 208.7) and moving downstream, are currently listed as impaired under California's Section 303(d) list for dissolved oxygen (SWRCB 2010a). Therefore, dissolved oxygen levels represent a significant cumulative effect for the Klamath River. Other cumulative projects or actions within the Klamath Basin that could decrease dissolved oxygen levels would include any that would increase suspended sediments, such as those noted above under suspended sediments. In addition, climate change impacts in the future could increase average ambient air and water temperatures, thus resulting in decreased and fluctuating dissolved oxygen content.

The Proposed Action's contribution to the cumulative effect on dissolved oxygen would be cumulatively considerable in the short term in the Hydroelectric Reach from J.C. Boyle Reservoir to Iron Gate Reservoir and in the Klamath River from Iron Gate Dam to the confluence with Clear Creek. While predicted short-term increases in oxygen demand under the Proposed Action generally result in dissolved oxygen concentrations that would meet the acceptable level (5 mg/L) for salmonids, exceptions to this would occur 4 to 8 weeks following drawdown of J.C. Boyle and Iron Gate reservoirs (i.e., in

February 2020), when dissolved oxygen would remain below 5 mg/L¹ from Iron Gate Dam to near the confluence with the Shasta River (RM 176.7), or for a distance approximately 20–25 km downstream from the dam. This analysis assumes that the effects of sediment release on short-term oxygen demand (and reductions in dissolved oxygen) in the Hydroelectric Reach downstream from J.C. Boyle Dam would be the same as those for the Lower Klamath River. Recovery to the North Coast Basin Plan water quality objective of 90 percent saturation (i.e., 10–11 mg/L) would occur within a distance of 100–150 km (62–93 mi) downstream from Iron Gate Dam, or generally in the reach from Seiad Valley to the mainstem confluence with Clear Creek, and would therefore not effect dissolved oxygen in the estuary or the nearshore environment. **The Proposed Action’s incremental contribution to the short-term significant cumulative effect associated with reductions in dissolved oxygen in the Klamath River downstream from J.C. Boyle Dam to the Oregon-California State line and the Lower Klamath River from Iron Gate Dam to Clear Creek during reservoir drawdown would be cumulatively considerable. No feasible mitigation is available to reduce this impact; therefore it remains cumulatively considerable.**

Removal of the Four Facilities under the Proposed Action could cause long-term (2–50 years following dam removal) increases in dissolved oxygen, as well as increased daily variability in dissolved oxygen, in the Hydroelectric Reach and in the Lower Klamath River, particularly for the reach immediately downstream from Iron Gate Dam. Modeling conducted for development of the Oregon and California Klamath River TMDLs indicates that under the Proposed Action (similar to the TMDL TOD2RN scenario), dissolved oxygen concentrations in the Hydroelectric Reach downstream from J.C. Boyle Dam and at the Oregon-California State line would be slightly greater during July through October than those under the No Action/No Project (similar to the TMDL T4BSRN scenario), due to the removal of J.C. Boyle Reservoir (Figure 3.2-15 and Figure 3.2-16; NCRWQCB 2010a). The same pattern is predicted for 30-day mean minimum and 7-day mean minimum dissolved oxygen criteria. The Klamath TMDL model (see Appendix D) also predicts that daily fluctuations in dissolved oxygen immediately downstream from J.C. Boyle Dam during this same period would be greater under the Proposed Action (TCD2RN) than the No Action/No Project Alternative (T4BSRN) (Figure 3.2-16). The slight increases in summer and fall dissolved oxygen concentrations and daily fluctuations downstream from J.C. Boyle Dam would be beneficial.

¹ Minimum acceptable dissolved oxygen concentration for salmonids. Although the minimum acceptable water quality objective for dissolved oxygen in the Klamath River for warm freshwater, saline, and marine habitats was previously 5 mg/L (NCRWQCB 2006), recent Basin Plan amendments require 85-90% saturation (generally ranging from 6–11 mg/L) depending on location and month (NCRWQCB 2010). Section 3.3 (Aquatics) of this EIS/EIR references a threshold of 6 mg/L for migrating adult anadromous salmonids (USEPA 1986), which is also a useful benchmark for dissolved oxygen concentrations. Based on BOD/IOD model results, a return to 6 mg/L dissolved oxygen would occur further downstream than the results presented in Table 3.2-13, on the order of 5–15 miles (10–25 km) depending on hydrologic conditions.

In contrast, the TMDL model predicts somewhat reduced daily fluctuations in dissolved oxygen at State line (i.e., in the Peaking Reach) under the Proposed Action (TCD2RN) as compared to the No Action/No Project Alternative (T4BSRN) (Figure 3.2-17). The slight decreases in daily fluctuations at the California-Oregon State line would be less than significant.

Additionally, elimination of the seasonal extremes in dissolved oxygen (i.e., supersaturation in surface waters and oxygen depletion in bottom waters) in the riverine reaches replacing Copco 1 and Iron Gate Reservoirs in the Hydroelectric Reach would occur under the Proposed Action and would be beneficial. In the Lower Klamath River immediately downstream from Iron Gate Dam, the removal of the Four Facilities under the Proposed Action would cause long-term increases in summer and fall dissolved oxygen along with potentially increasing daily variability due to the lack of stratification and oxygen depletion in bottom waters in the upstream reservoirs as compared with a free-flowing river condition (see Figure 3.2-18). Effects would diminish with distance downstream from Iron Gate Dam, such that there would be no measurable effects on dissolved oxygen by the confluence with the Trinity River.

As noted above, dissolved oxygen is a significant cumulative impact for the Klamath River. The Proposed Action's contribution to this cumulative effect would be beneficial as it would increase long-term dissolved oxygen concentrations in summer and fall and daily variability in dissolved oxygen and it would eliminate seasonal extremes in the riverine reaches replace Copco 1 and Iron Gate Reservoirs. **The Proposed Action's incremental contribution to the long-term significant cumulative effect associated with increases in summer and fall dissolved oxygen concentrations in the Hydroelectric Reach and immediately downstream from Iron Gate Dam would be beneficial.**

4.4.1.1.5 pH

Removal of the Four Facilities under the Proposed Action and conversion of the reservoir areas to a free-flowing river could result in short-term (<2 years following dam removal) and long-term (2–50 years following dam removal) decreases in summertime pH in the Hydroelectric Reach. Removal of the Four Facilities under the Proposed Action and conversion of the reservoir areas to a free-flowing river could result in long-term (2–50 years following dam removal) summertime increases in pH in the Lower Klamath River, the Klamath Estuary, and the marine nearshore environment. Klamath TMDL model results indicate that under the Proposed Action, pH in the Hydroelectric Reach immediately downstream from J.C. Boyle Dam would be the same as pH levels modeled under the No Action/No Project, with the potential for small decreases in minimum daily values. At the Oregon-California State line, pH levels under the Proposed Action would exhibit less daily variability during spring (March–May) and fall (October–November) while daily variability in the river during the period June–September would be similar or somewhat greater under the Proposed Action, likely due to enhanced periphyton growth in the free-flowing river reaches previously occupied by the upstream J.C. Boyle Reservoir.

Currently, reaches upstream of the Hydroelectric Reach (i.e., from RM 231 to RM 251, Upper Klamath Lake, Agency Lake, and the Sprague River) are included on Oregon's 303(d) list for pH, but the Hydropower Reach itself is not identified as impaired. A variety of different cumulative actions could contribute to changes in pH in this reach. Increased snowmelt or increased large storm events with heavy precipitation due to climate change, agricultural runoff, and acid rain could change pH in the Lower Klamath River. As the newly restored river erodes the river channel, the geology of the materials being eroded could alter the pH. Increases in pH could also occur from enhanced periphyton growth and increased rates of photosynthesis. These actions, considered together with the Proposed Action, could substantially change pH levels and result in significant cumulative water quality effects associated with pH.

The Proposed Action's contribution to the cumulative effect would be minimal. In the Hydroelectric Reach, there would be less daily variability of pH, and this would be beneficial. The modeled increases at the Oregon-California State line would consistently meet the Oregon water quality objective of 9.0 units for support of beneficial uses and would therefore be less than significant. While there are no TMDL model results for riverine locations upstream of Copco 1 or Iron Gate Reservoirs, these locations would be expected to exhibit similar patterns as those predicted for the Klamath River at the Oregon-California State line.

The Proposed Action would also eliminate the occurrence of high pH (> 9 pH units) and large (0.5–1.5 pH units) daily fluctuations occurring in the surface waters of Copco 1 and Iron Gate Reservoirs during periods of intense algal blooms. pH in the free-flowing reaches of the river replacing these reservoirs would not exhibit such extremes, instead possessing the riverine signal described above.

Modeling results indicate there would be large daily variation in pH and generally high pH levels in the Klamath River downstream from Iron Gate Dam under the Proposed action. Predicted differences in pH between the Proposed Action and No Action/No Project Alternative decrease in magnitude with distance downstream from Iron Gate Dam, and are considerably dampened by the Scott River confluence (RM 143.0). The Hoopa Valley Tribe water quality objective for pH (7.0-8.5) is met at all times under the Proposed Action (similar to the TMDL TCD2RN scenario) for the Klamath River at the reach of Hoopa jurisdiction (≈45–46).

Although the California Klamath River TMDL model predicts long-term increases in pH due to enhanced periphyton growth and increased rates of photosynthesis immediately downstream from Iron Gate Dam, this condition may be counteracted by increased scour and lack of nutrient availability at this location under the Proposed Action (see Section 3.4, Algae). Given the uncertainty in the model output from Iron Gate Dam to the Shasta River, and given the localized and instantaneous nature of the predicted high pH levels during summer months, these long-term pH increases would not be substantial. **The Proposed Action's incremental contribution to the significant short-term and long-term cumulative effect associated with slight summertime increases pH and daily pH fluctuations at the Oregon-California State line and upstream and**

downstream reaches that are currently riverine would not be cumulatively considerable. The Proposed Action's incremental contribution to the significant cumulative effect associated with decrease in high summertime daily pH fluctuations in the free-flowing reaches of the river that replace Copco 1 and Iron Gate Reservoirs in the Hydroelectric Reach would be beneficial. The Proposed Action's incremental contribution to the significant short-term and long-term cumulative effect associated with pH would not be cumulatively considerable from Iron Gate Dam to the Scott River. There would be no significant cumulative pH effects for the Klamath River downstream from the Scott River, the Klamath River Estuary and marine nearshore environment.

4.4.1.1.6 Chlorophyll-a and Algal Toxins

*Removal of the Four Facilities under the Proposed Action and conversion of the reservoir areas to a free-flowing river could cause short-term (<2 years following dam removal) and long-term (2–50 years following dam removal) decreases in levels of chlorophyll-a and algal toxins in the Hydroelectric Reach, the Lower Klamath River, and potentially the Klamath Estuary. Elimination of the lacustrine (reservoir) environment that currently supports growth conditions for toxin-producing nuisance algal species such as *M. aeruginosa* would result in decreases in high seasonal concentrations of chlorophyll-a (>10 µg/L) and periodically high levels of algal toxins (> 8 µg/L microcystin) generated by suspended blue-green algae. Additionally, growth of *M. aeruginosa* in reaches of the Klamath River downstream from Iron Gate Dam would be reduced in the absence of significant reservoir blooms.*

In the past, chlorophyll-a and algal toxins have resulted in a significant cumulative water quality impact in the Klamath River and have adversely affected aquatic species and human health. The main cumulative actions/projects contributing to chlorophyll-a and algal toxins are the construction of the KHP, which created reservoirs with conditions that promote nuisance algal growth, and nutrient loading from Upper Klamath Lake, as described above for nutrients. The Proposed Action's contribution to this cumulative effect would be beneficial. The Proposed Action would eliminate conditions promoting algal growth through reservoir drawdown and dam removal. **The Proposed Action's incremental contribution to the short-term and long-term significant cumulative water quality effect associated with a decrease in chlorophyll-a and a substantial decrease or elimination of algal toxins in the Hydroelectric Reach and subsequent transport into the Lower Klamath River and the potentially the Klamath Estuary would be beneficial.**

4.4.1.1.7 Inorganic and Organic Contaminants

Sediment release associated with the Proposed Action could cause short-term (<2 years following dam removal) and long-term (2–50 years following dam removal) increases in concentrations of inorganic and organic contaminants and result in low-level exposure for freshwater aquatic species in the Hydroelectric Reach, Lower Klamath River, Klamath Estuary, and marine nearshore environment. The Proposed Action could result in short-term (<2 years following dam removal) and long-term (2–50 years following dam removal) human exposure to contaminants from contact with deposited sediments on

exposed reservoir terraces, river banks in the Hydroelectric Reach, and downstream river banks following reservoir drawdown. Dam deconstruction and revegetation (i.e., hydroseeding) activities could cause short-term (<2 years following dam removal) increases in inorganic and organic contaminants from hazardous materials associated with construction and revegetation (i.e., hydroseeding) equipment in the Hydroelectric Reach, Lower Klamath River, Klamath Estuary, and marine nearshore environment. Under the Proposed Action, herbicide application associated with management of the reservoir footprint area could result in short-term (<2 years following dam removal) levels of organic contaminants in runoff that are toxic to aquatic biota in the Hydroelectric Reach. The Proposed Action would result in the release of organic and inorganic contaminants through reservoir drawdown and the release of sediment, use of hazardous materials associated with construction and revegetation, and the application of herbicides. Short-term pathways of contaminant exposure for freshwater aquatic species include exposure during sediment transit through the Lower Klamath Basin river reaches and the estuary, as well as exposure following initial deposition of sediments in the river and the estuary. Potential human health risks could occur with exposure to sediments deposited on exposed reservoir terraces and river banks within the Hydroelectric Reach.

In general, information regarding contaminants in the Upper Klamath Basin upstream of the Hydroelectric Reach is very limited. Human activities such as illegal dumping may be a source of inorganic and organic contaminants to the lower Sprague and Williamson river sub-basins (Rabe and Calonje 2009). Natural geologic sources of arsenic may be causing relatively high levels of this chemical element in the Upper Klamath Basin (see Appendix C.7.1 for more detail). Other ongoing actions such as agricultural activities that result in the use of herbicides or pesticides, or large forest fires, may contribute to an increase in inorganic and organic contaminants in the Klamath River through surface water runoff or atmospheric deposition. Together, these actions could combine to result in significant cumulative effects associated with inorganic and organic contaminants.

The Proposed Action's incremental contribution to the significant cumulative effects associated with inorganic and organic contaminants would be minimal. Results from the 2009–2010 Secretarial Determination sediment chemistry analyses indicate that sediment deposits associated with the Proposed Action show that one or more chemicals are present, but at levels unlikely to cause adverse effects based on the lines of evidence (CDM 2011). Previous studies and the 2009–2010 Secretarial Determination study (CDM 2011) indicate that in the short term (<2 years following dam removal), one or more chemicals would be present at levels with potential to cause minor or limited adverse effects on freshwater aquatic species. In the long term, one or more chemicals would be present, but at levels unlikely to cause adverse effects based on the lines of evidence. Implementation of BMPs for deconstruction and revegetation activities that would occur in or adjacent to the Klamath River would minimize the potential for chemicals in sediment to enter the water. With respect to bioaccumulation potential, there are no detected chemicals that exceeded applicable marine bioaccumulation screening levels (CDM 2011). Elutriate chemistry results (prior to consideration for mixing and dilution) do not indicate likely toxicity in the marine nearshore environment

under the Proposed Action (CDM 2011). **The Proposed Action's incremental contribution to the significant cumulative effects associated with inorganic and organic contaminants would not be cumulatively considerable.**

KBRA - Programmatic Measures

Implementation of the Phase I Fisheries Restoration Plan could result in long-term reductions in fine sediment inputs, reduced summer water temperatures, improved nutrient interception, and increased dissolved oxygen levels. Implementation of the Phase II Fisheries Restoration Plan under the KBRA (KBRA Section 10.2) would include a continuation of the same types of resource management actions as under Phase I along with provisions for adaptive management of these actions and would therefore have the same short-term (i.e., during construction activities) and long-term impacts as Phase I. Implementation of the trap and haul element of the Fisheries Reintroduction and Management Plan could affect water quality during construction. Implementation of Wood River Wetland Restoration could result in warmer long-term spring water temperatures and reduced fine sediment and nutrient inputs to Upper Klamath Lake. Implementation of Water Diversion Limitations could result in long-term decreased summer water temperatures in the Klamath River upstream of the Hydroelectric Reach. Implementation of the WURP could result in long-term decreases in summer water temperature and nutrient inputs to Upper Klamath Lake. Implementation of the Interim Flow and Lake Level Program could result in long-term decreases in summer water temperature and nutrient inputs to Upper Klamath Lake. Implementation of the Upper Klamath Lake and Keno Nutrient Reduction Program could result in long-term decreases in nutrient inputs, increases in seasonal dissolved oxygen, and decreases in concentrations of nuisance algal species in these waterbodies. Many KBRA actions have the potential to affect water quality conditions in the various waterways of the Klamath Basin.

As noted above, temperature, sediment, nutrients, and dissolved oxygen continue to represent significant adverse cumulative water quality effects for the Klamath River. A variety of actions, mainly human-related activities, have contributed to these cumulative impacts. There are also many ongoing actions in the Klamath Basin to improve water quality, including the implementation of TMDLs on the Scott, Salmon, Shasta, and Klamath Rivers as noted in Table 4-3, the Hoopa Valley Tribe Water Quality Control Plan (Hoopa Valley Indian Reservation 2008), the Water Quality Control Plan by the Yurok Tribe (2004), and the Draft Eco-Cultural Resources Management Plan (2010) by the Karuk Tribe that contain measures and programs to improve water quality, various watershed and creek restoration projects by the Hoopa Valley Tribe and Siskiyou County noted in Table 4-4, and the Five Counties Road Maintenance Program. Additionally, the Northwest Forest Plan contains provisions for reducing water quality impacts from timber harvesting and road construction. Together these cumulative actions and programs would contribute to improving water quality in the Klamath Basin. Removal of the Four Facilities is also expected to help improve water quality by restoring the reservoirs to a more natural river system and reducing conditions that promote algal growth.

The KBRA's incremental contribution to the cumulative effects on water quality would be minimal in the short term and would generally be beneficial in the long term. In the short term, some of the KBRA actions could require construction activities that would have the potential to adversely affect water quality. However, best management practices would be implemented to reduce or avoid water quality impacts. In the long term, the KBRA actions are intended to be beneficial to water quality by improving water temperatures, reducing fine sediment and nutrient inputs, and increasing dissolved oxygen levels. **The KBRA's incremental contribution to the significant cumulative effects on water quality would not be cumulatively considerable in the short term and would be beneficial in the long term.**

4.4.1.2 Alternatives 3, 4, and 5

Alternatives 3 and 5 would have similar cumulative short-term and long-term effects on water quality (i.e., water temperature, suspended sediments, nutrients, dissolved oxygen, pH, chlorophyll-a, algal toxins, and inorganic and organic contaminants) as the Proposed Action. Although only two reservoirs are removed under Alternative 5, they are the two largest reservoirs in the Hydroelectric Reach and are responsible for the majority of water quality impacts under existing conditions. Alternative 4 would leave all four reservoirs in place. No short-term cumulative effects associated with high suspended sediment concentrations and low dissolved oxygen due to reservoir drawdown would occur under Alternative 4; however, long-term water quality would not improve and therefore there would be no cumulative benefits. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; therefore there would be no cumulative effects associated with KBRA actions.

4.4.1.3 Mitigation Measures

There would be short-term cumulatively considerable impacts associated with suspended sediment and decreased dissolved oxygen levels during drawdown under the Proposed Action, the Partial Facilities Removal of Four Dams Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative. No feasible mitigation is possible to reduce the impacts during reservoir drawdown. Suspended sediment concentrations would remain a cumulatively considerable water quality impact for up to 6-10 months following reservoir drawdown. Dissolved oxygen levels would remain a cumulatively considerable impact for up to 2 years after reservoir drawdown.

4.4.2 Aquatic Resources

Cumulative effects on aquatic resources could be caused by short-term and long-term effects on water and quality and habitat associated with the project, combined with other projects/actions in the Klamath Basin that could contribute to adverse aquatic resources effects. The timeframe for short-term construction related cumulative effects analysis is the duration of deconstruction and up to 10 months after reservoir drawdown, as suspended sediments are expected to remain elevated. The timeframe for long-term cumulative effects is indefinitely after construction as conditions for aquatic species would be permanently altered with implementation of any of the proposed alternatives.

Table 4-6 presents a summary of the aquatic resources impacts identified in Chapter 3. These impacts are then analyzed for cumulative effects below the table.

4.4.2.1 Alternative 2: Full Facilities Removal of Four Dams

4.4.2.1.1 Critical Habitat

The Proposed Action could alter the availability and quality of critical habitat, which could affect aquatic species.

Coho Salmon Critical Habitat

Under the Proposed Action, elevated levels of suspended sediment concentrations occurring during 3 to 4 months of drawdown would degrade critical habitat for coho salmon in the short term.

Agricultural water diversions, timber harvesting, man-made barriers such as the Four Hydroelectric dams, mining, road building, livestock grazing, and streambed alteration have contributed to the degradation of coho salmon critical habitat (64 Federal Register 24049). While no specific activities have been identified that would affect coho salmon critical habitat during reservoir drawdown, ongoing activities such as agriculture, water diversions, and mining, and poor water quality could all contribute to the degradation of critical habitat. Degradation of critical habitat is therefore a significant cumulative impact in the short term.

The Proposed Action's contribution to the significant cumulative effect on critical habitat would be substantial. There would be 3 to 4 months of high suspended sediment concentrations that would degrade critical habitat for coho salmon.

However, in the long term, the Proposed Action would increase the amount of habitat available to coho salmon upstream of currently designated critical habitat and improve habitat quality within current critical habitat. Bedload movement following dam removal would cause substantial aggradation and increase supply of gravel below the dam as far downstream as Cottonwood Creek. This effect would potentially improve critical habitat for coho salmon by reducing median substrate to a size more favorable for spawning (Reclamation 2012). Other cumulative actions and programs that could benefit critical habitat for coho salmon include the Trinity River Restoration Program, the Five Counties Road Management Program, and the Klamath Basin Conservation Area Restoration Program, which would improve water quality and habitat in the Klamath River.

Table 4-6. Summary of Aquatic Resources Impacts from Chapter 3

- SSC = suspended sediment concentrations

The Northwest Forest Plan would reduce impacts from timber harvesting and road construction on aquatic species and habitat and may benefit coho salmon critical habitat. Other stream and watershed restoration actions, such as those being completed by the Hoopa Valley Tribe and Siskiyou County (see Table 4-4) could also improve critical habitat for coho salmon. Together, these actions and the Proposed Action would result in cumulatively beneficial effects on coho salmon critical habitat. **The Proposed Action's incremental contribution to the significant cumulative effect on coho salmon critical habitat would be cumulatively considerable in the short term during reservoir drawdown, and would be beneficial in the long term. No feasible mitigation is available to reduce the short-term significant cumulative impacts; therefore they remain cumulatively considerable.**

Bull Trout Critical Habitat

Implementation of the Proposed Action would not affect the physical or chemical components of bull trout critical habitat, but would allow Chinook salmon and steelhead to access areas they have not been able to access since the completion of the Copco 1 Development in 1918. These species would potentially compete with and prey upon bull trout fry and juveniles; however, bull trout would also be expected to consume the eggs and fry of Chinook salmon and steelhead. These species co-evolved in the watershed together, and it is anticipated that they would be able to co-exist in the future.

Past and present threats to bull trout critical habitat include channelization, water withdrawals, removal of streamside vegetation, elevated water temperatures, and increased sedimentation (United States Fish and Wildlife Service [USFWS] 2002). Degradation of bull trout critical habitat is a significant cumulative impact.

The Proposed Action would not physically alter the bull trout critical habitat. **The Proposed Action's incremental contribution to the significant cumulative effect on bull trout critical habitat would not be cumulatively considerable in the short or long term.**

Southern Resident Killer Whale Critical Habitat

The Klamath River contributes to critical habitat for Southern Resident Killer Whales through its contribution of Chinook salmon to their food supply. The Proposed Action would not affect the geographic extent of critical habitat for this species, as it is located in the State of Washington. The Proposed Action is expected to increase wild populations of anadromous salmonids, which could increase food supply for Southern Resident Killer Whale.

One of the Primary Constituent Elements for the Southern Resident Killer Whale critical habitat is "Prey species of sufficient quantity, quality and availability to support individual growth, reproduction and development, as well as overall population growth" (National Oceanic and Atmospheric Administration [NOAA] Fisheries Service 2006). The Southern Resident Killer Whale population has declined substantially since the mid- to late 1800s. The declining population is partially attributed to a decline in food

sources, including stocks of fish, whales, and pinnipeds (NOAA Fisheries Service 2006). Changes to salmon populations, one of their main food sources, are therefore considered a significant cumulative effect on critical habitat.

The Proposed Action’s contribution to the cumulative effect would be minimal. While the Proposed Action is anticipated to increase salmon populations, the Klamath River salmon are anticipated to provide less than 1 percent of the diet of Southern Resident Killer Whale in most months. **The Proposed Action’s incremental contribution to the significant cumulative effect on Southern Resident killer whale critical habitat would not be cumulatively considerable.**

Eulachon Critical Habitat

Under the Proposed Action, PCEs of critical habitat supporting eulachon would be degraded in the short term, including short-term adverse effects of suspended sediment on spawning and egg incubation habitat, and adult and larval migration habitat for southern Distinct Population Segment eulachon.

Eulachon populations have declined substantially since the 1960s. Past and ongoing habitat and other protective efforts have contributed to the conservation of the southern DPS, but these efforts have not sufficiently reduced the extinction risks. Past and present actions affecting eulachon critical habitat include the presence of the four hydroelectric dams (Iron Gate, J.C. Boyle and Copco 1 and Copco 2), which have affected and continue to affect water flow, water quality, substrate quality, and depth. Timber harvesting and road building actions have also affected critical habitat by increasing sediment loading to aquatic environments (National Marine Fisheries Service [NMFS] 2011). Changes to water quality therefore considered significant cumulative effects on critical habitat.

The Proposed Action’s contribution to the short-term significant cumulative effects would be cumulatively considerable during reservoir drawdown because it would increase suspended sediments. Over the long term, the Proposed Action’s contribution to the significant cumulative effect is expected to be beneficial. Under the Proposed Action it is anticipated that water quality would improve throughout the Klamath River, including the estuary (WQST 2011) and that habitat restoration effort under KBRA would improve estuary habitat. **The Proposed Action’s incremental contribution to the significant cumulative effect on eulachon critical habitat would be cumulatively considerable in the short term during reservoir drawdown, and would be beneficial in the long term. No feasible mitigation is available to reduce the short-term significant cumulative impacts; therefore they remain cumulatively considerable.**

4.4.2.1.2 Essential Fish Habitat

The Proposed Action would alter the availability of Essential Fish Habitat (EFH), which could affect aquatic species.

Chinook and Coho Salmon EFH

The release of sediment from reservoirs under the Proposed Action would adversely affect Chinook and coho salmon EFH in the short term during the months when suspended sediment concentrations are elevated. Over the long term, the Proposed Action would benefit EFH.

Past and present actions have also affected Chinook and coho salmon EFH. Agricultural water diversions, man-made barriers, including the four hydroelectric dams, sedimentation from erosion and runoff, and alteration of stream channels have affected water quality, fish passage, and food sources for salmon. While no other specific activities have been identified that would affect salmon EFH during reservoir drawdown, existing practices such as agriculture, water diversions, mining, and dredging could all contribute to the degradation of essential habitat. Together these actions have had significant cumulative effects on Chinook and coho salmon EFH.

The Proposed Action's contribution to the short-term cumulative effect would be substantial. There would be 3 to 4 months of high suspended sediment concentrations that would degrade Chinook and coho salmon EFH.

In the long term the Proposed Action would increase habitat for Chinook and coho salmon (upstream of currently designated EFH) by providing access to habitats upstream of Iron Gate Dam, improved water quality, and decrease prevalence of disease would provide a benefit to EFH for Chinook and coho salmon. Other cumulative actions and programs that could benefit Chinook and coho salmon EFH include the Trinity River Restoration Program, the Five Counties Road Management Program, and the Klamath Basin Conservation Area Restoration Program, which would improve water quality and habitat in the Klamath River. The Northwest Forest Plan would reduce impacts from timber harvesting and road construction on aquatic species and habitat and may benefit Chinook and coho salmon EFH. Other stream and watershed restoration actions, such as those being completed by the Hoopa Valley Tribe and Siskiyou County (see Table 4-4) could also improve critical habitat for Chinook and coho salmon EFH. Together, these actions and the Proposed Action would result in cumulatively beneficial effects on Chinook and coho salmon EFH. **Overall, the Proposed Action's incremental contribution to the significant cumulative effect on Chinook and coho salmon EFH would be cumulatively considerable in the short term and would be beneficial in the long term. No feasible mitigation is available to reduce the short-term significant cumulative impacts; therefore they remain cumulatively considerable.**

Groundfish EFH

Under the Proposed Action, EFH in the estuary could be affected by elevated turbidity from sediment releases during dam removal for about 3 months. After this time, suspended sediment concentrations would return to levels similar to existing conditions. Suspended sediment concentrations in the estuary would be less than 40 percent of the peak concentrations that are anticipated to occur immediately downstream from Iron Gate

Dam. These peaks would still be substantial, and would be higher than the extreme values estimated by the sediment transport model for existing conditions (see Section 3.3.4.5, Aquatic Resources).

Groundfish EFH continues to be adversely affected by commercial fishing. Certain types of common fishing gear, such as trawls, have degraded groundfish EFH. Non-fishing activities that have degraded EFH include mining, dredging, fill, impoundment, discharge, water diversions, thermal additions, actions that contribute to non-point source pollution and sedimentation, introduction of potentially hazardous materials, introduction of exotic species, and the conversion of aquatic habitat that may eliminate, diminish, or disrupt the functions of EFH (Pacific Fishery Management Council 2005). Together these actions have resulted in significant cumulative effects on groundfish EFH. The Proposed Action's contribution to the significant cumulative effects would be short term. Under the Proposed Project under the most likely to occur scenario, suspended sediment concentrations would be elevated relative to existing conditions, but would last a short duration. In the long term, suspended sediment concentrations would be similar to that under existing conditions. **The Proposed Action's contribution to the significant cumulative effect on EFH would not be cumulatively considerable.**

Pelagic Fish EFH

The cumulative effects on pelagic fish EFH would be similar to those described for groundfish EFH. **The Proposed Action's contribution to the significant cumulative effect on EFH would not be cumulatively considerable.**

4.4.2.1.3 Construction-Related Impacts

Disturbance to the river channel during construction could affect aquatic species. These effects could include shockwaves associated with breaking down the dam structure using explosives or heavy equipment, potential crushing of aquatic species from operation of heavy equipment in the river, sedimentation, and release of oil, gasoline, or other toxic substances from construction sites.

Other cumulative actions that could affect aquatic species during construction include agricultural activities, timber harvesting, new road construction, and mining that could increase suspended sediments, and construction projects in the surrounding area such as new subdivisions and road improvements planned in Siskiyou County that could introduce sediments or toxic materials into the river. Together these actions could result in cumulative effects on aquatic species.

The Proposed Action's contribution to the cumulative effect would not be cumulatively considerable. To reduce these potential construction impacts, construction areas would be isolated from the active river where possible, and water would be routed around the construction area, allowing the flow to move down the other portion of the river, while the isolated portion of the dam is removed. After a work area is isolated, fish rescues to remove any native fish trapped in the work area would be conducted. Fish would be relocated to an area of suitable habitat within the Klamath River. Implementation of soil erosion and sedimentation control and stormwater pollution prevention would minimize

soil erosion and water quality effects on anadromous fish downstream from the work area, during and after construction. **The Proposed Action's incremental contribution to the significant cumulative effects on aquatic resources during deconstruction would not be cumulatively considerable.**

4.4.2.1.4 Species-Specific Impacts

The Proposed Action could affect aquatic species.

Fall-Run Chinook Salmon

Reservoir drawdown associated with dam removal under the Proposed Action could alter SSCs and bedload sediment transport and deposition and affect fall-run Chinook salmon.

Overall, the effect of the Proposed Action on the fall-run Chinook salmon population, under both most-likely and worst-case scenarios, is expected to be relatively minor. Effects would be distributed over three year-classes, rather than a single year-class. Direct mortality is predicted for 2,100 redds (around 8 percent of total redds in the basin), and for around 669 Type III smolts (< 1 percent of production). In addition, sublethal effects on Type I and Type II outmigrants are predicted.

Significant cumulative effects have occurred to fall-run Chinook salmon in the Klamath Basin. Chinook salmon population levels have declined significantly over the last 100 years and currently a substantial number of Chinook salmon and coho salmon that return to spawn in the Klamath Basin were spawned in hatcheries (NOAA Fisheries Service 2009). Cumulative actions substantially affecting fall-run Chinook salmon include the construction of the KHP and other dams, which have severely reduced access to habitat, altered water quality, adversely affected channel morphology, and created conditions for toxic algal blooms. Downstream from Iron Gate Dam, the mainstem Klamath River experiences occasional blooms of *Microcystis aeruginosa*. During outmigration, in some years juvenile Chinook salmon are subject to elevated disease levels that persist due to continued reduced flow variability (as compared to more natural flow conditions) below Iron Gate Dam and limited dispersal of salmonid carcasses due to the presence of Iron Gate Dam and the Iron Gate Hatchery. These pathogens include myxozoan parasites *Parvicapsula minibicornis* and *Ceratomyxa shasta*. Dams have affected the quality of habitat downstream by preventing spawning gravel from traveling downstream (Moyle et al. 2008), releasing limited, warm, and sometimes toxic water, and dictating unnatural stream morphology or structure. It is also important to note that bedload sediment movement and transport are vital to create and maintain functional aquatic habitat. Bedload sediment, in the form of sand, gravels, cobbles and boulders is naturally delivered to and transported in undammed streams and rivers. Natural sediment pulses that result from heavy rainfall and snowmelt events are incorporated by stream and river processes into spawning beds, gravel bars, side channels, pools, riffles and floodplains that provide habitat and support food chains of aquatic species. These periodic inputs of bedload sediments are necessary for the long-term maintenance of aquatic habitats.

Salmonids evolved with sediment and depend on continued bedload sediment delivery to provide substrate suitable for spawning and early rearing in streams and rivers. These

processes have been disrupted by the dams. Other cumulative activities that have affected Chinook salmon include agriculture, grazing, water diversions, timber harvesting, mining, suction dredging, discharge of toxic substances such as fertilizers or pesticides into the river, overfishing, disease, and predation. There are also many ongoing cumulative actions and programs that are intended to reduce impacts or benefit Chinook salmon and habitat in the long term. The implementation of the Klamath Basin TMDLs would improve water quality. The Trinity River Restoration Program, the Five Counties Road Management Program, and the Klamath Basin Conservation Area Restoration Program would also help to improve water quality and aquatic habitat in the Klamath River. The Northwest Forest Plan would reduce impacts from timber harvesting and road construction on aquatic species and habitat. Other stream and watershed restoration actions, such as those being completed by the Hoopa Valley Tribe and Siskiyou County (see Table 4-4) could also improve habitat for Chinook salmon.

The Proposed Action’s incremental contribution to the short-term significant cumulative effect on fall-run Chinook salmon would be cumulatively considerable. The Proposed Action’s contribution to the cumulative effects would be reduced by implementing Mitigation Measures AR-1 through AR-4 to reduce the short-term impacts of suspended sediment concentrations on fall-run Chinook salmon incubating eggs, and smolts. Additionally, Type-II and Type-III progeny of adults that successfully spawn in tributaries during 2020 would produce smolts that outmigrate to the ocean a year after the spring pulse of suspended sediment in 2020 and should not be noticeably affected by the Proposed Action. However, because of the reduced growth, stress, and high reported mortality for Chinook salmon smolts, the suspended sediment concentrations would still have a substantial cumulative effect in the short term. **The Proposed Action’s incremental contribution to the short-term significant cumulative effect on fall-run Chinook salmon would be cumulatively considerable, even with mitigation. No other feasible mitigation is possible to reduce this impact; therefore this impact remains cumulatively considerable.**

Under the Proposed Action, removal of dams could alter habitat availability, flow regime, water quality, temperature variation, fish disease incidence, and algal toxins, all of which could affect fall-run Chinook salmon in the long term. Dam removal would restore connectivity to hundreds of miles of historical habitat in the Upper Klamath Basin and would create additional spawning and rearing habitat within the Hydroelectric Reach currently under reservoirs and of exceptional value to anadromous salmonids. The presence of the dams prevents anadromous salmonids from occupying this habitat. Access to habitat is essential to restore salmonid populations. It is anticipated that as a result of the Proposed Action, the fall-run Chinook salmon population within the Klamath River watershed would have an increase in abundance, productivity, population spatial structure, and genetic diversity. Restored migration to habitat above the dams is likely to enable a greater diversity of life history strategies and habitat utilization, with some of those strategies more likely to avoid periods of poor water quality, parasite exposure, and adverse effects of climate change than under current conditions. Dam removal would also cause water temperatures to become warmer earlier in the spring and summer and cooler earlier in the late summer and fall, and to have diurnal variations

more in sync with historical migration and spawning periods (Hamilton et al. 2011). These changes would result in water temperature more favorable for salmonids in the mainstem. Dam removal would maximize the recruitment of gravel within and downstream from the Hydroelectric Reach, which would benefit fish spawning in the entire mainstem Klamath River from at least the current site of Copco Reservoir to Cottonwood Creek. Additionally, more variable flows patterns under Alternatives 2 and 3 would more frequently mobilize bedload sediment such as sand, gravel, and cobbles, and restore more natural sediment transport processes. These conditions are likely to reduce the occurrence of juvenile salmon disease and create better conditions for migration, rearing, and spawning.

The Proposed Action's contribution to the significant cumulative effects on fall-run Chinook salmon would be beneficial in the long term by providing access to habitat, improving water quality, minimizing disease, and generally contributing to an increase in abundance, productivity, population spatial structure, and genetic diversity. **The Proposed Action's incremental contribution to the long-term significant cumulative effects on fall-run Chinook salmon would be beneficial.**

Spring-Run Chinook Salmon

Reservoir drawdown associated with dam removal under the Proposed Action could alter suspended sediment concentrations and bedload sediment transport and deposition and affect spring-run Chinook salmon. The overall effect of suspended sediment from the Proposed Action on the spring-run Chinook salmon population is not anticipated to differ much from existing conditions. There would be very little effect on adult migrants, and no effects are anticipated for the spawning, incubation, and fry stages. Type I and II outmigrants are expected to experience very similar conditions under the Proposed Action as under existing conditions and the No Action/No Project Alternative. However, direct mortality is predicted for around 16 to 28 Type III smolts (< 1 percent of production). In addition, sublethal effects on adult migrants and Type I and Type II outmigrants are predicted.

Chinook salmon population levels have declined significantly over the last 100 years and currently a substantial number of Chinook salmon and coho salmon that return to spawn in the Klamath Basin were spawned in hatcheries (NOAA Fisheries Service 2009). Cumulative actions substantially affecting spring-run Chinook salmon are similar to those described above for fall-run Chinook salmon.

The Proposed Action's incremental contribution to the significant cumulative effect on spring-run Chinook salmon would be cumulatively considerable. However, the cumulative impact would be reduced by implementing Mitigation Measure AR-2 to reduce the short-term impacts of suspended sediments on spring-run Chinook salmon Type III smolts. **With mitigation measures AR-2, the Proposed Action's incremental contribution to the short-term significant cumulative effect on spring-run Chinook salmon from sediment release would not be cumulatively considerable.**

Under the Proposed Action, removal of dams could result in alterations in habitat availability, flow regime, water quality, temperature variation, and fish disease incidence, and algal toxins which could affect spring-run Chinook salmon in the long term. Dam removal would restore connectivity to hundreds of miles of potentially usable habitat in the Upper Klamath Basin and would create additional spawning and rearing habitat within the Hydroelectric Reach. Restored migration to habitat above the dams is likely to enable a greater diversity of life history strategies and habitat utilization, with some of those strategies more likely to avoid periods of poor water quality, parasite exposure, and adverse effects of climate change than under current conditions.

Significant cumulative effects have occurred to spring-run Chinook salmon in the Klamath Basin. Chinook salmon population levels have declined significantly over the last 100 years and currently a substantial number of Chinook salmon and coho salmon that return to spawn in the Klamath Basin were spawned in hatcheries (NOAA Fisheries Service 2009). Cumulative actions substantially affecting spring-run Chinook salmon are similar to those described above for fall-run Chinook salmon.

The Proposed Action’s incremental contribution to significant cumulative effects on spring-run Chinook salmon would be beneficial. It is anticipated that as a result of the Proposed Action, the spring-run Chinook salmon population within the Klamath River watershed would have an increase in abundance, productivity, population spatial structure, and genetic diversity by providing access to additional habitat and improving water quality. **The Proposed Action’s incremental contribution to the long-term significant cumulative effects on spring-run Chinook salmon would be beneficial.**

Coho Salmon

Reservoir drawdown associated with dam removal under the Proposed Action could alter suspended sediment concentrations and bedload sediment transport and deposition and affect coho salmon. In general, the wide distribution and use of tributaries by both juvenile and adult coho salmon would likely protect the population from the worst effects of the Proposed Action. However, direct mortality is anticipated for around 13 redds, or 0.7–26 percent of Upper Klamath River Population unit natural escapement. Direct mortality is also anticipated for 2,668 smolts under the most-likely to occur scenario, or 6,536 smolts under a worst-case scenario. This equates to no mortality for the Salmon River, Trinity River, and Lower Klamath River populations under the most likely or worst-case scenarios, and 9 percent of the production from the Upper Klamath River, Mid-Klamath River, Shasta River, and Scott River population units, or 22 percent under a worst-case scenario. Sublethal effects are anticipated for all other life-stages. All population units would be expected to recover from these losses within one or two generations, given the long-term benefits described below. Although no single year-class is expected to be completely lost, mortality of a portion of the smolt outmigration from the Upper Klamath River, Mid-Klamath River, Shasta River, and Scott River population units may affect the strength of the 2018 year class, requiring two or three generations to recover from losses.

Significant cumulative effects have occurred to coho salmon in the Klamath Basin. Coho salmon population levels have declined significantly over the last 100 years, and currently a substantial number of Chinook salmon and coho salmon that return to spawn in the Klamath Basin were spawned in hatcheries (NOAA Fisheries Service 2009). A large variety of actions have contributed to significant cumulative adverse effects on coho salmon, including the Klamath Hydroelectric Project. Additionally, alterations of the natural flow regimes have increased water temperatures, depleted flows necessary for migration, spawning, rearing, flushing of sediments from spawning gravels, gravel recruitment and transport of bedload and large woody debris. Land use activities in the Klamath Basin such as logging, road construction, urban development, mining, agriculture, and recreation have altered habitat quantity and quality, resulting in increased stream bank erosion, increased sedimentation input and loss of channel complexity (NOAA Fisheries Service Undated). Some ongoing actions that would also benefit coho salmon in the long term include implementation of Klamath Basin TMDLs to improve water quality, the Trinity River Restoration Program, the Five Counties Road Management Program, and the Klamath Basin Conservation Area Restoration Program, which would improve water quality and habitat in the Klamath River. The Northwest Forest Plan would reduce impacts from timber harvesting and road construction on aquatic species and habitat. Several anadromous fish reintroduction and conservation plans developed by the Tribes and the Oregon Department of Fish and Wildlife would help to conserve coho salmon and their habitat and support restoration efforts. Other stream and watershed restoration actions, such as those being completed by the Hoopa Valley Tribe and Siskiyou County (see Table 4-4) could also improve habitat for coho salmon.

The Proposed Action's incremental contribution to the cumulative effect would be cumulatively considerable; however it would be lessened by implementing Mitigation Measures AR-1 through AR-4 to reduce the short-term impacts of suspended sediment concentrations on coho salmon adults, incubating eggs, and smolts. With implementation of mitigation measures there would still be short term effects for coho salmon including direct mortality to as high as 18 percent of the smolts from some population units under a worst-case scenario. **The Proposed Action's incremental contribution to the short-term significant cumulative effect on coho salmon would remain cumulatively considerable even with mitigation AR-1 through AR-4. No additional feasible mitigation is available to further reduce this cumulative impact; therefore it remains cumulatively considerable.**

Under the Proposed Action, removal of dams could result in alterations in habitat availability, flow regime, water quality, temperature variation, and fish disease incidence, and algal toxins which could affect coho salmon in the long term. Dam removal would restore connectivity to habitat on the mainstem Klamath River up to and including Spencer Creek and would create additional habitat within the Hydroelectric Reach. Dam removal would also cause water temperatures to become warmer earlier in the spring and early summer and cooler earlier in the late summer and fall, and to have diurnal variations more in sync with historical migration and spawning periods (Hamilton et al. 2011). These changes would result in water temperature more favorable for

salmonids in the mainstem. It is anticipated that as a result of the Proposed Action the Upper Klamath River, Mid-Klamath River, Shasta River, Scott River, Salmon River, and Lower Klamath River coho salmon population units would have an increase in abundance, productivity, population spatial structure, and genetic diversity. It is anticipated that as a result of the Proposed Action the three Trinity River population units would have increased productivity.

Significant cumulative effects have occurred to coho salmon in the Klamath Basin. Coho salmon population levels have declined significantly over the last 100 years, and currently a substantial number of Chinook salmon and coho salmon that return to spawn in the Klamath Basin were spawned in hatcheries (NOAA Fisheries Service 2009). A large variety of actions have contributed to significant cumulative adverse effects on coho salmon, including the Klamath Hydroelectric Project. Additionally, alterations of the natural flow regimes have increased water temperatures, depleted flows necessary for migration, spawning, rearing, flushing of sediments from spawning gravels, gravel recruitment and transport of bedload and large woody debris. Land use activities in the Klamath Basin such as logging, road construction, urban development, mining, agriculture, and recreation have altered habitat quantity and quality, resulting in increased stream bank erosion, increased sedimentation input and loss of channel complexity (NOAA Fisheries Service Undated). Some ongoing actions would also benefit coho salmon in the long term include implementation of Klamath Basin TMDLs to improve water quality, the Trinity River Restoration Program, the Five Counties Road Management Program, and the Klamath Basin Conservation Area Restoration Program, which would improve water quality and habitat in the Klamath River. The Northwest Forest Plan would reduce impacts from timber harvesting and road construction on aquatic species and habitat. Several anadromous fish reintroduction and conservation plans developed by the Tribes and the Oregon Department of Fish and Wildlife would help to conserve coho salmon and their habitat and support restoration efforts. Other stream and watershed restoration actions, such as those being completed by the Hoopa Valley Tribe and Siskiyou County (see Table 4-4) could also improve habitat for coho salmon.

Based on increased habitat availability and improved habitat quality, **the Proposed Action's incremental contribution to the significant long-term cumulative effects on coho salmon would be beneficial for the coho salmon from the Upper Klamath River, Mid-Klamath River, Lower Klamath River, Shasta River, Scott River, and Salmon River population units in the long term and would not be cumulatively considerable for coho salmon from the three Trinity River population units in the long term.**

Steelhead

Reservoir drawdown associated with dam removal under the Proposed Action could alter suspended sediment concentrations and bedload sediment transport and deposition and affect steelhead. Effects of suspended sediment resulting from the Proposed Action on steelhead are likely to be high, particularly for the portion of the population that spawns

in tributaries upstream of the Trinity River. For that portion of the population, effects are anticipated on adults, run-backs, half-pounders, any juveniles rearing in the mainstem, and outmigrating smolts.

Significant cumulative effects have occurred on steelhead populations in the Klamath River, including degraded habitat, decreased habitat access, fish passage, predation, and competition (Moyle et al. 2008). Steelhead populations are generally believed to have decreased since the early 1900's. This is likely due to degraded habitat and blocked tributaries (National Research Council 2004).

The Proposed Action's incremental contribution to the cumulative effect on steelhead would be cumulatively considerable; however it would be reduced by the implementation of Mitigation Measures AR-2 and AR-3. These measures would reduce the short-term impacts of suspended sediment concentrations on steelhead adults and outmigrating juveniles. Additionally, the broad spatial distribution of steelhead in the Klamath basin and their flexible life history suggests that some would avoid the most serious effects of the Proposed Action by (1) remaining in tributaries for extended rearing, (2) rearing farther downstream where SSC should be lower due to dilution (e.g., the progeny of the adults that spawn in the Trinity River basin or tributaries downstream from the Trinity River), and/or (3) moving out of the mainstem into tributaries and off-channel habitats during winter. In addition, the life-history variability observed in steelhead means that, although numerous year classes would be affected, not all individuals in any given year class would be exposed to the effects of the Proposed Action. In addition, some portion of the progeny of those adults that spawn successfully would rear in tributaries long enough to not only avoid the most serious impacts of the Proposed Action in 2020, but may also not return to spawn for up to two years, when any suspended sediment resulting from the Proposed Action should be greatly reduced. The high incidence of repeat spawning among summer-run steelhead (ranging from 40 to 64 percent, Hopelain 1998) should also increase that population's resilience (including all year classes) to effects of the Proposed Action. However, because of the potential for reduction in the abundance of a year class in the short term, **the Proposed Action's incremental contribution to the significant cumulative effects on summer and winter steelhead would be cumulatively considerable even with mitigation measures AR-2 and AR-3. No other feasible mitigation is available to reduce this impact; therefore it remains cumulatively considerable.**

Under the Proposed Action, removal of dams could result in alterations in habitat availability, flow regime, water quality, temperature variation, and algal toxins which could affect steelhead in the long term. Dam removal would restore connectivity to hundreds of miles of historical habitat in the Upper Klamath Basin and would create additional habitat within the Hydroelectric Reach. It is anticipated that as a result of the Proposed Action the summer and winter steelhead within the Klamath River watershed would have an increase in abundance, productivity, genetic diversity and the opportunity for variable life histories and use of new habitats.

Other cumulative actions that would also benefit steelhead in the long term include implementation of Klamath Basin TMDLs to improve water quality. Several anadromous fish reintroduction and conservation plans developed by the Tribes and the Oregon Department of Fish and Wildlife would help to conserve steelhead and their habitat and support recovery efforts. Together, these actions could benefit steelhead in the long term. **The Proposed Action’s incremental contribution to the long-term significant cumulative effects on steelhead would be beneficial.**

Pacific Lamprey

Reservoir drawdown associated with dam removal under the Proposed Action could alter suspended sediment concentrations and bedload sediment transport and deposition and affect Pacific lamprey. The elevated suspended sediment concentrations under the Proposed Action could adversely affect the Lamprey population. Because multiple year classes of lamprey rear in the mainstem Klamath River at any given time, and since adults would migrate upstream over the entire year, including January 2020 when effects from the Proposed Action would be most pronounced, effects on Pacific lamprey adults and ammocoetes could be high in the mainstem Klamath River. However, most of the population would likely avoid the most severe suspended sediment pulses resulting from the Proposed Action. In addition, Pacific lamprey are considered to have low fidelity to their natal streams, and may not enter the mainstem Klamath River if environmental conditions are unfavorable in 2020. Migration into the Trinity River and other Lower Klamath River tributaries may also increase during 2020 because of poor water quality. Low fidelity also increases the potential that lamprey can recolonize mainstem habitat if ammocoetes rearing there suffer high mortality.

Significant cumulative effects have occurred on various life history stages of the Pacific lamprey, including manmade barriers to migration, water quality, predation, stream and floodplain degradation, dredging, and disease (USFWS 2009). The Proposed Action’s incremental contribution to the short-term cumulative effect on Pacific lamprey would be cumulatively considerable based on substantial reduction in the abundance of a year class in the short term. Implementation of Mitigation Measures AR-2 and AR-5 would be implemented to reduce the short-term impacts of suspended sediment concentrations on lamprey ammocoetes. However, with implementation of mitigation measures there could still be short-term effects for lamprey including sublethal and lethal effects. **The Proposed Action’s incremental contribution to the short-term significant cumulative effect on lamprey would remain cumulatively considerable even with mitigation measures AR-2 and AR-5. No other feasible mitigation is available to reduce this impact; therefore it would be cumulatively considerable.**

Under the Proposed Action, removal of dams could result in alterations in habitat availability, flow regime, water quality, and temperature variation which could affect Pacific lamprey in the long term. The Proposed Action would provide access to habitat in the Hydroelectric Reach and tributaries to this reach. It is anticipated that as a result of the Proposed Action the Pacific lamprey population within the Klamath River watershed would have an increase in abundance, productivity, population spatial structure, and genetic diversity. Other cumulative actions that could also contribute benefits to this

species include several anadromous fish reintroduction and conservation plans developed by the Tribes and the Oregon Department of Fish and Wildlife would help to conserve Pacific lamprey and their habitat and support recovery efforts, and water quality improvements as described under salmon and steelhead. Together, these actions would have cumulative benefits on Pacific lamprey. **The Proposed Action's incremental contribution to the long-term significant cumulative effect on Pacific lamprey would be beneficial.**

Green Sturgeon

Reservoir drawdown associated with dam removal under the Proposed Action could alter suspended sediment concentrations and affect green sturgeon. Up to 100 percent mortality is predicted for incubating eggs and larval life stages, and up to 20 percent mortality is predicted for rearing juveniles under a most-likely-to-occur scenario, or up to 40 percent mortality under a worst-case scenario. Overall, the effects of the Proposed Action are most likely to include physiological stress, inhibited growth, and high mortality for some portion of the age-0 2020 cohort and age 1 2019 cohort. Green sturgeon populations have severely decreased over time, and while little information is available on the cumulative impacts to green sturgeon, because of their small population, it is assumed that green sturgeon have experienced significant adverse cumulative effects.

The Proposed Action's incremental contribution to the short-term cumulative effect on green sturgeon would be cumulatively considerable. Mitigation Measure AR-3 would be implemented to reduce the short-term impacts of suspended sediment concentrations on green sturgeon adults post-spawning; however, there would still be short-term impacts to green sturgeon including lethal and sublethal effects. **The Proposed Action's incremental contribution to the short-term significant cumulative effects on green sturgeon would remain cumulatively considerable even with mitigation measure AR-3. No other mitigation is available to reduce suspended sediment concentrations; therefore this impact remains cumulatively considerable.**

Under the Proposed Action, removal of dams could result in alterations in flow regime, water quality, temperature variation, and algal toxins which could affect green sturgeon in the long term. It is anticipated that as a result of the Proposed Action the green sturgeon population within the Klamath River watershed would have an increased productivity based on improved habitat conditions. As noted above, significant cumulative effects on green sturgeon exist due to their small population. **The Proposed Action's incremental contribution to the long-term significant cumulative effects on green sturgeon would not be cumulatively considerable.**

Lost River and Shortnose Sucker

Reservoir removal associated with dam removal under the Proposed Action could alter habitat availability and affect Lost River and shortnose suckers. The Proposed Action would eliminate reservoir habitat for the Lost River and shortnose suckers. However, this habitat is of little or no significance in restoring these species. Lost River and shortnose suckers have experienced significant cumulative effects from loss of habitat and decline in general water quality. Toxic algal blooms have also resulted in large fish

kills. Water reclamation projects that have removed a substantial number of wetlands in the Upper Klamath Basin have severely affected the quantity and quality of sucker habitat. Water diversions, dredging of Upper Klamath Lake, and the draining of marshes have also contributed to cumulative effects on suckers.

The Proposed Action's incremental contribution to cumulative effects on Lost River and shortnose suckers would be cumulatively considerable. Impacts to these suckers would be minimized by implementing Mitigation Measure AR-6 and removing individuals prior to reservoir drawdown. Based on the small number of individuals affected after mitigation, **the Proposed Action's incremental contribution to significant short-term significant cumulative effects on Lost River and shortnose suckers would not be cumulatively considerable with implementation of mitigation measure AR-6.**

Redband Trout

The Proposed Action would have short-term effects related to suspended sediment concentrations and bed load movement that could affect redband trout. Redband trout in riverine reaches between the reservoirs in the Hydroelectric Reach would be vulnerable to sublethal and lethal effects of sediment released during dam removal and bed load deposition. However, in the long term, bedload sediment movement and transport are vital to create and maintain functional aquatic habitat. Bedload sediment, in the form of sand, gravels, cobbles and boulders is naturally delivered to and transported in undammed streams and rivers. Natural sediment pulses that result from heavy rainfall and snowmelt events are incorporated by stream and river processes into spawning beds, gravel bars, side channels, pools, riffles and floodplains that provide habitat and support food chains of aquatic species. These periodic inputs of bedload sediments are necessary for the long-term maintenance of aquatic habitats.

Salmonids evolved with sediment and depend on continued bedload sediment delivery to provide substrate suitable for spawning and early rearing in streams and rivers. These processes have been disrupted by the dams.

Redband trout in the Klamath River have experienced significant adverse cumulative effects as a result of existing conditions. The construction of the Klamath Hydroelectric Project has obstructed passage and reduced habitat, and has also adversely altered stream flows and water quality. Redband trout in the Klamath Hydroelectric Project reach are subject to ongoing entrainment into hydroelectric generation facilities and effect to habitat due to peaking. Other past and present cumulative impacts to Redband trout in the Klamath River include agricultural and timber harvesting practices which have degraded stream habitat, channelization and sedimentation of the river, irrigation, and water diversions. As a result of these impacts, some streams and populations are fragmented and have lost connection to lakes and marshes (Oregon Department of Fish and Wildlife 2010).

The Proposed Action's contribution to cumulative effects on redband trout would be short term and minimal. While the release of suspended sediment could affect this

species, a large proportion of the adult population should be already spawning in Spencer or Shovel creeks during the dam removal. Juvenile redband trout outmigrating from Spencer Creek would be expected to recolonize the mainstem by late spring or summer when water conditions become suitable. Those in the affected area could move to tributaries for refuge. The initial movement of coarse and fine sediment after drawdown would likely create adverse conditions for redband trout within the mainstem Klamath River, but these conditions would be short term. **Therefore, the Proposed Action's incremental contribution to significant cumulative effects on redband trout would not be cumulatively considerable in the short term.**

Dam removal would restore connectivity among the Lower Klamath Basin, the Hydroelectric Reach and its tributaries, and the upper basin, and would rehabilitate and increase availability of riverine habitat within the Hydroelectric Reach. As noted above, significant cumulative effects as a result of existing conditions have occurred to redband trout. Salmonids, including redband trout, have depend on continued bedload sediment delivery to provide substrate suitable for spawning and early rearing in streams and rivers. These processes have been disrupted by the dams. Based on increased habitat availability, restored migration, and improved habitat quality, the effect of the Proposed Action would be beneficial for redband trout in the long term. **The Proposed Action's incremental contribution to the significant cumulative impact on redband trout would be beneficial in the long term.**

Bull Trout

Dam removal associated with the Proposed Action could alter habitat availability for anadromous fish, which could affect bull trout. Bull trout upstream of Upper Klamath Lake could be affected by increased predation from reintroduced salmonids, but this loss might be offset by an increase in available food sources (e.g., eggs, fry, and juveniles of reintroduced salmonids) (Hamilton et al. 2010).

Bull trout have experienced significant cumulative adverse impacts. Bull trout populations in the Klamath Basin have been severely reduced and fragmented. Cumulative actions and projects that have contributed to their decline include channelization, water withdrawals, removal of streamside vegetation, timber harvesting practices, and other actions that have degraded the aquatic environment by elevating water temperatures, reducing water quantity and quality, and increasing sedimentation. Klamath Basin bull trout face a high risk of extirpation and continue to be threatened by habitat degradation, past and present land use management practices, agricultural water diversions, and competition or hybridization from nonnative brown and brook trout (USFWS 2002).

The Proposed Action's contribution to the significant cumulative effects on predation of bull trout would be counteracted by the increase in food source that would become available from eggs, fry, and juveniles of reintroduced salmonids. Additionally, Buchanan et al. (2011) states that the Proposed Action provides promise for preventing

extinction of bull trout and for increasing overall population abundance and distribution. **Therefore, the Proposed Action’s incremental contribution to the significant cumulative effect on bull trout would not be cumulatively considerable in the short term or the long term.**

Eulachon

The Proposed Action would have short term effects related to suspended sediment concentrations and bedload movement. The Proposed Action would release dam-stored sediment downstream to the Lower Klamath River. Adults entering the Klamath River in the winter and spring of 2020 may be exposed to high suspended sediment concentrations for a portion of their migration period. Although no analysis of the effects of suspended sediment concentrations on eulachon is available, based on application of the Newcombe and Jensen (1996) approach using studies of the effects on other estuary species, it is predicted that under a most-likely or worst-case scenario mortality would be higher under the Proposed Action than under existing conditions. Mortality is also predicted to be higher for spawning, incubation, and larval life stages under the Proposed Action than under existing condition.

Significant cumulative adverse effects have occurred to eulachon populations in the Klamath River. Eulachon abundance in the Klamath River is in decline and eulachon spawning populations have severely declined and may become endangered in the future. The main cumulative impacts that threaten eulachon are identified by NOAA Fisheries Service as climate change impacts and ocean conditions, eulachon bycatch, dams/water diversions, water quality, dredging, and predation (NOAA Fisheries Service 2010). Other substantial cumulative impacts include in-water construction or alterations, including channel modifications, shoreline stabilization, sand and gravel mining, and road building and maintenance and pollution and runoff from industrial activities, urbanization, grazing, agriculture, and forestry operations (NOAA Fisheries Service 2010).

The Proposed Action would have short-term impacts on eulachon from increased suspended sediment concentrations during reservoir drawdown. However, there are two key factors that reduce the likelihood that substantial numbers of individuals will be exposed. First, eulachon are very rare in the Klamath River, and thus there is a very low probability that any individuals will be in the Klamath River during implementation of the Proposed Action. Second, eulachon have a relatively long period of the year when they could potentially spawn in the Klamath River (January through April; Larson and Belchik 1998), and a relatively short duration of occurrence within freshwater (around one month), increasing the probability that most of the population would migrate and spawn either before or after the largest pulses of suspended sediment concentrations (predicted to be two weeks in duration or less). Because there would be no substantial reduction in the abundance of a year class, and there would be only a short duration of poor water quality during reservoir drawdown in the estuary, **the Proposed Action’s incremental contribution to the significant cumulative effect would not be cumulatively considerable in the short term or the long term.**

Longfin Smelt

The Proposed Action would have short term effects related to suspended sediment concentrations and bedload movement. The Proposed Action would release dam-stored sediment downstream to the Lower Klamath River. Longfin smelt entering the Klamath River in the winter and spring of 2020 might be exposed to elevated suspended sediment concentrations for a portion of their migration period.

The overall abundance of longfin smelt has declined to very low levels. Significant adverse cumulative effects on longfin smelt have occurred from diversion of surface water, predation, and bycatch in a commercial fishery. They have also been adversely affected by dredging and sand mining, and are susceptible to adverse effects from toxic substances in the water and in the plankton upon which the fish feed.

The Proposed Action would have short-term impacts on longfin smelt from increased suspended sediment concentrations during reservoir drawdown. However, as described for eulachon above, the protracted migration season for longfin smelt (throughout the year), and relatively short duration of occurrence in the estuary (<2 months), increasing the probability that most of the population would migrate and spawn either before or after the largest pulses of suspended sediment concentrations (predicted to be two weeks in duration or less). Based on the short-term nature of the water quality effects, the long term impacts would not be cumulatively considerable. **The Proposed Action's incremental contribution to the significant cumulative effects on longfin smelt would not be cumulatively considerable in the short term and long term.**

Introduced Resident Species

The Proposed Action would eliminate habitat for introduced resident species in the Hydroelectric Reach. Because these species were introduced and they occur in other nearby water bodies, their loss would not be considered significant from a biological perspective, and would benefit native species. No other cumulative actions or programs would eliminate a substantial amount of habitat in the Klamath River for introduced resident species. **There would be no significant cumulative effects associated with the loss of habitat for introduced resident species.**

Freshwater Mussels

The Proposed Action would have short term effects related to suspended sediment concentrations and bedload movement. The Proposed Action could affect freshwater mussels through the release of sediments during reservoir drawdown. Very little information exists on population trends in the Klamath River; therefore, it is difficult to determine if other cumulative actions or projects have contributed to significant cumulative effects on freshwater mussels. For the purposes of this analysis, it is assumed that significant cumulative effects have occurred to freshwater mussels from ongoing activities that have increased suspended sediments in the Klamath River, such as timber harvesting, road construction, mining, and agricultural activities.

The Proposed Action's incremental contribution to this short-term significant cumulative effect would be substantial. The suspended sediment concentrations would cause major

physiological stress to freshwater mussels and might result in substantial mortality. The most significant impacts would occur downstream from Iron Gate Reservoir, especially to those individual freshwater mussels or freshwater mussel beds upstream of Orleans and closest to Iron Gate Dam. While it is anticipated that mainstem Klamath freshwater mussel populations would rebound, due to the extended time it takes for freshwater mussels to reach sexual maturity (4 years or more, depending on the species), the reestablishment of freshwater mussel populations within affected reaches might be slow and might not be readily noticeable for some time, possibly a decade or more. Implementation of Mitigation Measure AR-7 could be implemented to reduce the short- and long-term impacts of the Proposed Action on freshwater mussels. With implementation of mitigation measures there would still be impacts to a portion of the freshwater mussel population, and there could still be a substantial reduction in the abundance of at least one year class. **The Proposed Action’s incremental contribution to the short-term significant cumulative effects on freshwater mussels would be cumulatively considerable even with mitigation.**

Dam removal would restore connectivity among the Lower Klamath Basin, the Hydroelectric Reach and its tributaries, and the Upper Klamath Basin, and would rehabilitate and increase availability of riverine habitat within the Hydroelectric Reach. Based on increased habitat availability and habitat quality in the long term, the effect of the Proposed Action would be beneficial for mussels in the long term. It is assumed that significant cumulative effects have occurred to freshwater mussels from ongoing activities that have increased suspended sediments in the Klamath River, such as timber harvesting, road construction, mining, and agricultural activities. Several ongoing or planned activities in the basin to address water quality and sediment (listed in Table 4-3), together with the Proposed Action, would likely contribute to beneficial cumulative effects. **The Proposed Action’s incremental contribution to the long-term cumulative effects on freshwater mussels would be beneficial.**

Benthic Macroinvertebrates

The Proposed Action would have short term effects related to suspended sediment concentrations and bedload movement. Under the Proposed Action, increased suspended-sediment concentrations would be expected to result in cumulative effects on filter-feeding benthic macroinvertebrates similar to that as described for freshwater mussels. Cumulative effects on benthic macroinvertebrates are assumed to be similar to those described above for freshwater mussels. While a large proportion of macroinvertebrate populations in the Hydroelectric Reach and in the mainstem Klamath River downstream from Iron Gate Dam would be affected in the short term by the Proposed Action, their populations would be expected to recover quickly because of the many sources for recolonization and their rapid dispersion through drift or aerial movement of adults. **The Proposed Action’s incremental contribution to the short-term significant cumulative effects on benthic macroinvertebrates would be cumulatively considerable. No feasible mitigation is available to reduce this impact; therefore it remains cumulatively considerable.**

Dam removal would restore connectivity among the Lower Klamath Basin, the Hydroelectric Reach and its tributaries, and the upper basin, and would rehabilitate and increase availability of riverine habitat within the Hydroelectric Reach. The impacts of hydropower peaking on benthic macroinvertebrates would be eliminated. The reformation of river channels in the reservoir reaches upstream of Iron Gate Dam under the Proposed Action would benefit benthic macroinvertebrates by providing more suitable substrates than currently exist. As a result, suitable habitats formed upstream of Iron Gate Dam might be opened to additional colonization by benthic macroinvertebrates through rapid dispersal by drift from upstream populations within current riverine reaches and/or dispersion of adult life stages. In addition, recolonization would occur rapidly from established benthic macroinvertebrate populations within the many tributary rivers and streams of the Klamath River. Several ongoing or planned activities in the basin to address water quality and sediment (listed in Table 4-3), together with the Proposed Action, would likely contribute to beneficial cumulative effects. **The Proposed Action's incremental contribution to the long-term cumulative effects on benthic macroinvertebrates would be beneficial.**

4.4.2.1.5 Interim Measures

Implementation of IMs 7 (J.C. Boyle Gravel Placement and/or Habitat Enhancement) and 16 (Water Diversions) could result in alterations to habitat availability and habitat quality, and affect aquatic species. These IMs would increase spawning gravel or habitat upstream of Copco Reservoir and would increase flows in Shovel and Negro Creeks. As described above, past and present cumulative projects have resulted in significant cumulative effects to resident and anadromous fish species. These IMs would provide improvements in habitat quantity and quality for resident fish prior to dam removal, and for resident and anadromous species following dam removal. Other cumulative ongoing and planned restoration and habitat improvement activities listed in Table 4-3 above would also contribute to cumulative benefits on habitat quantity and quality. **Therefore, the Proposed Action's incremental contribution to the significant cumulative effects would be beneficial for fall-run Chinook salmon, spring-run Chinook salmon, steelhead, Pacific lamprey, redband trout, and benthic macroinvertebrates. These actions would also be cumulatively beneficial for coho salmon from the Upper Klamath River Population Unit. Cumulative effects on bull trout, freshwater mussels, shortnose and Lost River suckers would not be cumulatively considerable.**

4.4.2.1.6 KBRA

Implementation of Phases I and 2 Fisheries Restoration Plans and Fisheries Monitoring Plan could result in alterations to water quantity, water quality, habitat availability and habitat quality, and affect aquatic species. Implementation of Phase I of the Fisheries Reintroduction and Management Plan could result in alterations to habitat availability (fish access), and could affect aquatic species. The Phases I and 2 Fisheries Restoration Plans and Fisheries Monitoring Plans are designed to improve habitat for aquatic species. The Phase I Fisheries Reintroduction and Management Plan is intended to support the reintroduction and management of fish in the upper basin during and after implementation of the KHSA.

As described above, significant cumulative effects have occurred to many fish species and habitat in the Klamath Basin as a result of the existing conditions. However, there are several ongoing cumulative actions or programs that are intended to improve fisheries in the Klamath River and its tributaries, including the removal of the Four Facilities as part of the KHSA, the Trinity River Restoration Program, the Five Counties Road Management Program, and the Klamath Basin Conservation Area Restoration Program. With implementation of the KBRA, ongoing habitat restoration would be better funded, better coordinated and monitored to ensure effective implementation.

The Northwest Forest Plan contains provisions to reduce impacts from timber harvesting on aquatic species and habitat. Other stream and watershed restoration actions, such as those being completed by the Hoopa Valley Tribe and Siskiyou County (see Table 4-4), would also improve fisheries.

The KBRA's incremental contribution to the significant cumulative effects on fisheries would be beneficial. These KBRA actions would improve habitat and potentially increase the number of anadromous fish. Increased anadromous fish abundance, especially Chinook salmon, would result in more prey availability for Southern Resident Killer Whales when the whales are near the Oregon and California coasts. Based on anticipated improvements in water quantity, water quality, habitat availability and habitat quality, these actions would be beneficial for fall-run Chinook salmon, spring-run Chinook salmon, steelhead, Pacific lamprey, redband trout, benthic macroinvertebrates, and shortnose and Lost River suckers. These actions would also be beneficial for coho salmon, except those in the Trinity River population units. **The incremental contribution of the Fisheries Restoration Plans, Fisheries Monitoring Plans, and Fisheries Reintroduction and Management Plan to the significant cumulative effects on Klamath Basin fisheries would be beneficial. Implementation of the KBRA will require future environmental compliance as appropriate.**

Implementation of Water Diversion Limitations could result in reducing uncertainties associated with maintaining adequate ecological flows for aquatic species and their habitats, especially in low-flow years, and could alter water quality and water temperatures in certain seasons and affect aquatic species. Implementation of the On-Project Plan could result in alterations to water quantity and water quality and affect aquatic species. This component of the KBRA would establish limits on specific diversions within Reclamation's Klamath Project to protect flows in the mainstem and ensure that adequate water supply is available for allocation to the wildlife refuges.

The KBRA's incremental contribution to the significant cumulative effects on fisheries would be beneficial and go beyond these current programs and recovery of listed species, advancing salmonid fisheries to greater levels.. Based on anticipated improvements in water quantity and water quality, implementation of Water Diversion Limitations under the Proposed Action would be beneficial for fall-run Chinook salmon, spring-run Chinook salmon, steelhead, Pacific lamprey, redband trout, and shortnose and Lost River suckers. These actions would also be beneficial for coho salmon, except those in the Trinity River population units. **The incremental contribution of Water Diversion**

Limitations to the significant cumulative effects on fisheries would be beneficial. Implementation of the KBRA will require future environmental compliance as appropriate.

Implementation of the Fish Entrainment Reduction could result in potential alterations to mortality risk and affect aquatic species. This KBRA action would involve designing and installing fish screens at Project Diversions, including the Lost River Diversion Channel and associated diversion points, North Canal, Ady Canal, and other Reclamation and Reclamation Contractor diversions.

As noted above, significant cumulative impacts have occurred to Klamath Basin fisheries. Additionally, there are many other cumulative actions and programs that would also restore fisheries and habitat in the Klamath Basin. The Proposed Action's incremental contribution to the significant cumulative effect on fisheries would be beneficial. The Fish Entrainment Reduction would reduce mortality caused by entrainment of fish at these diversions, to the benefit of endangered shortnose and Lost River suckers, as well as to redband trout. Steelhead and fall- and spring-run Chinook salmon, steelhead, Pacific lamprey, and coho salmon would also benefit from this action once they recolonize areas upstream of Keno Dam. **The incremental contribution of Fish Entrainment Reduction to the cumulative effect would be beneficial. Implementation of the KBRA will require future environmental compliance as appropriate.**

Implementation of the Interim Flow and Lake Level Program could result in decreases in summer water temperature and nutrient inputs to Upper Klamath Lake. The KBRA includes a program to study and reduce nutrient concentrations in the Keno Impoundment/Lake Ewuana and Upper Klamath Lake in order to reduce dissolved oxygen problems and algal problems in both water bodies. Restoration actions to control nutrients have not been developed, and there are many diverse possibilities that could require construction of treatment wetlands, construction of facilities, or chemical treatments of bottom sediment, among other possibilities. A nutrient reduction program in the Keno Impoundment/Lake Ewuana and Upper Klamath Lake would be designed to improve water quality (increasing dissolved oxygen and reducing algal concentration) and to provide fish passage through the Keno Impoundment/Lake Ewuana in summer and fall months; however, implementation of this nutrient reduction program will require future environmental compliance investigations and a determination on the significance of cumulative effects cannot be made at this time. Implementation of the KBRA will require future environmental compliance as appropriate.

4.4.2.2 Alternatives 3, 4, and 5

Alternative 3 and 5 would have similar cumulative effects on aquatic resources as the Proposed Action; however, two dams would remain in place under Alternative 5, reducing the amount of habitat and resulting in fewer water quality improvements. Alternative 4 would involve the creation of fish passage facilities but all four dams would remain in place. No short-term cumulative effects associated with suspended sediment concentrations from reservoir drawdown would occur to aquatic species; however, water

quality issues would not improve and therefore there would be no cumulative benefits from improved water quality. Because all four dams would remain in place, some habitat would still be blocked by the presence of the reservoirs. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; therefore there would be no cumulative effects associated with KBRA actions.

4.4.2.3 Mitigation Measures

While there would be cumulatively considerable impacts on aquatic species from Alternatives 2, 3, and 5 even with mitigation, no additional feasible mitigation is available to reduce these impacts. These impacts would remain cumulatively considerable.

4.4.3 Algae

Potential cumulative effects on the phytoplankton and periphyton communities would occur mainly through changes in temperature, light, and nutrient levels in the Klamath River. The timeframe for the cumulative effects analysis associated with reservoir drawdown is the length of deconstruction. The timeframe for long-term cumulative effects after deconstruction is indefinite, as conditions promoting algae growth would be permanently altered with implementation of any of the proposed alternatives.

Table 4-7 presents a summary of the algae impacts described in Chapter 3. These impacts are analyzed for cumulative effects below the table.

Table 4-7. Summary of Algae Impacts from Chapter 3

Potential Impact	Alternatives	Significance	Mitigation	Significance after Mitigation
Upper Klamath Basin Upstream of the Influence of J.C. Boyle Reservoir				
Dam removal activities would not affect phytoplankton in the Klamath River upstream of J.C. Boyle Reservoir.	2, 3, 5	NCFEC	None	NCFEC
Dam removal activities would not affect periphyton in the Klamath River upstream of J.C. Boyle Reservoir.	2, 3, 5	NCFEC	None	NCFEC
Hydroelectric Reach				
Continued impoundment of water in the reservoirs could support the long-term growth of seasonal nuisance and/or noxious phytoplankton such as <i>M. aeruginosa</i> in the Hydroelectric Reach.	1, 4	NCFEC	None	NCFEC
Sediment release associated with dam removal could cause short-term increases in sediment-associated nutrients downstream from J.C. Boyle Dam that could stimulate nuisance and/or noxious phytoplankton	2, 3	NCFEC	None	NCFEC

Table 4-7. Summary of Algae Impacts from Chapter 3

Potential Impact	Alternatives	Significance	Mitigation	Significance after Mitigation
growth in the Hydroelectric Reach.				
Removal of the reservoirs would eliminate lacustrine habitat behind the dams and could decrease or eliminate the long-term spatial extent, temporal duration, or concentration of nuisance and/or noxious phytoplankton blooms in the Hydroelectric Reach and subsequent transport to the Klamath River from downstream from Iron Gate Dam to the Klamath Estuary.	2, 3, 5	B	None	B
Sediment release associated with the Proposed Action could cause short-term increases in sediment-associated nutrients downstream from J.C. Boyle Dam that could stimulate nuisance periphyton growth in the Hydroelectric Reach.	2, 3	NCFEC	None	NCFEC
Dam removal, conversion of the reservoir areas to a free-flowing river, and the elimination or reduction of hydropower peaking operations could cause long-term increases in nuisance periphyton growth due to increases in available habitat along low-gradient channel margin areas downstream from J.C. Boyle Dam.	2, 3, 5	S	None	S
Increased water temperatures and decreased peaking flows could result in long-term small amounts of nuisance periphyton colonization in the Klamath River downstream from J.C. Boyle Reservoir and upstream of Copco 1 Reservoir.	4	LTS	None	LTS
Implementation of IM 7, J.C. Boyle Gravel Placement and/or Habitat Enhancement, could result in increased bedload mobility and the potential for increased scour of nuisance periphyton in the Hydroelectric Reach.	1, 2, 3	B	None	B
<i>Klamath River Downstream from Iron Gate Dam</i>

Potential Impact	Alternatives	Significance	Mitigation	Significance after Mitigation
Klamath Basin Restoration Agreement – Programmatic Measures				
Implementation of restoration actions, programs, and/or plans presented in the KBRA would accelerate restoration actions currently underway throughout the Klamath Basin and reduce nuisance and/or noxious phytoplankton blooms through their beneficial effects on flow and water quality.	2, 3	B	None	B
Implementation of the Phase I Fisheries Restoration Plan could result in a long-term reduction in nutrients and associated decreases in nuisance and/or noxious phytoplankton and periphyton blooms.	2, 3	B	None	B
Implementation of the Phase II Fisheries Restoration Plan under the KBRA (KBRA Section 10.2) would include a continuation of the same types of resource management actions as under Phase I along with provisions for adaptive management of these actions and would therefore have the same impacts as Phase I.	2, 3	B	None	B
Implementation of Wood River Wetland Restoration could result in reduced nutrient inputs to Upper Klamath Lake and associated decreases in nuisance and/or noxious phytoplankton blooms.	2, 3	B	None	B
Implementation of the Water Use Retirement Program could result in decreases in nutrient inputs to Upper Klamath Lake and associated decreases in nuisance and/or noxious phytoplankton blooms.	2, 3	B	None	B
Implementation of the Interim Flow and Lake Level Program could result in decreases in nutrient inputs to Upper Klamath Lake and associated decreases in nuisance and/or noxious phytoplankton blooms.	2, 3	B	None	B

Table 4-7. Summary of Algae Impacts from Chapter 3

Potential Impact	Alternatives	Significance	Mitigation	Significance after Mitigation
Implementation of the Upper Klamath Lake and Keno Nutrient Reduction Program could result in decreases in nutrient inputs to Upper Klamath Lake and Keno Impoundment/Lake Ewuana and associated decreases in nuisance and/or noxious phytoplankton blooms.	2, 3	N/A ¹	N/A	N/A

A nutrient reduction program in the Keno Impoundment/Lake Ewauna and Upper Klamath Lake would be designed to improve water quality (increasing seasonally low dissolved oxygen and reducing seasonal algal blooms) and fish passage through the Keno Impoundment/Lake Ewauna in summer and fall months, however implementation of this nutrient reduction program will require future environmental compliance investigations and a determination on significance cannot be made at this time.

S = Significant

N/A = Not Applicable

LTS = Less than Significant

The main cumulative action affecting algae growth is the construction and operation of the KHP. The stable lacustrine environment created at the Four Facilities, particularly in the larger Copco 1 and Iron Gate Reservoirs, coupled with high nutrient availability and high water temperatures in summer to fall, provides ideal conditions for phytoplankton growth. Past and present actions potentially contributing to algal growth include agricultural activities, grazing, and sedimentation, which have increased nutrient loading in the Klamath River. Future cumulative actions with the potential to affect algae include implementation of the Klamath Basin TMDLs.

4.4.3.1 Alternative 2: Full Facilities Removal of Four Dams**4.4.3.1.1 Phytoplankton**

Sediment release associated with the Proposed Action could cause short-term increases in sediment-associated nutrients downstream from J.C. Boyle Dam that could stimulate nuisance and/or noxious phytoplankton growth in the Hydroelectric Reach. Under the Proposed Action, the short-term increase in nutrients due to the mobilization of sediment-associated nitrogen and phosphorus in the Hydroelectric Reach would have a minimal impact on phytoplankton due to the timing of reservoir drawdown.

Blue-green algae reach very high densities in the summer months in the Klamath Basin. Some blue-green algae produce toxins that are harmful to fish, mammals and humans (see Section 3.2.3.7, Water Quality). The Klamath River from Copco 1 Reservoir (RM 203.1) to Iron Gate Dam (RM 190.1) is listed as impaired for toxicity due to the

presence of microcystin in the reservoirs (see Section 3.2.2.3, Water Quality). Blue-green algae growth therefore represents a significant cumulative effect.

The Proposed Action's contribution to the short-term cumulative effects associated with nuisance and/or noxious phytoplankton growth would not be cumulatively considerable. By mid-to late- spring when phytoplankton begin to bloom again, reservoir drawdown would be nearly complete and little to no quiescent habitat would remain in the Hydroelectric Reach. Thus, phytoplankton blooms, and in particular nuisance and/or noxious phytoplankton blooms, would be very limited if not absent from the Hydroelectric Reach. **The Proposed Action's incremental contribution to the significant cumulative effects on nuisance and/or noxious phytoplankton growth in the short term would not be cumulatively considerable.**

Under the Proposed Action, removal of the reservoirs at the Four Facilities would eliminate lacustrine habitat behind the dams and could decrease the long-term spatial extent, temporal duration, or concentration of nuisance and/or noxious phytoplankton blooms. Under the Proposed Action, removal of the reservoirs would eliminate lacustrine habitat behind the dams and could substantially reduce or eliminate the long-term transport of nuisance and/or noxious phytoplankton blooms and concentrations of algal toxins into the Klamath River downstream from Iron Gate Dam. Under the Proposed Action, removal of the reservoirs would eliminate lacustrine habitat behind the dams and could substantially reduce or eliminate the long-term transport of nuisance and/or noxious phytoplankton blooms and concentrations of algal toxins into the Klamath Estuary. In the long term, dam removal, particularly within the larger Copco 1 and Iron Gate Reservoirs, would decrease or eliminate the system's support for excessive growth of blue-green algae by eliminating large areas of quiescent habitat where these algal species currently thrive. This dramatic decrease in the amount of optimal habitat available for nuisance and/or noxious phytoplankton species would occur even if relatively high nutrient concentrations were to remain in the Klamath River system. This would substantially reduce seasonal phytoplankton bloom occurrence and the associated production of algal toxins in these reservoirs that are potentially harmful to animals and humans. Additionally, because it is evident that large seasonal blue-green algae blooms (i.e., *M. aeruginosa*) and associated algal toxins (i.e., microcystin) in Copco 1 and Iron Gate Reservoirs and the Klamath River downstream from Iron Gate Dam originate in the two largest Project reservoirs and are transported to Klamath River sites downstream from Iron Gate Dam, the overall occurrence of nuisance and/or noxious phytoplankton and associated toxins in the Klamath River downstream from Iron Gate Dam would be substantially reduced or eliminated under the Proposed Action. Because removal of the Four Facilities would reduce or eliminate elevated *M. aeruginosa* levels in the lower Klamath River (see prior section), levels in the Klamath Estuary are also likely to be reduced or eliminated.

Blue-green algae reach very high densities in the summer months in the Klamath Basin. Some blue-green algae produce toxins that are harmful to fish, mammals and humans (see Section 3.2.3.7, Water Quality). The Klamath River from Copco 1 Reservoir (RM 203.1) to Iron Gate Dam (RM 190.1) is listed as impaired for toxicity due to the

presence of microcystin in the reservoirs (see Section 3.2.2.3, Water Quality). Blue-green algae growth represents a significant cumulative effect.

The Proposed Action's contribution to cumulative effects associated with blue-green algae would be beneficial by eliminating habitat through removal of the dams, and by reducing transport of nuisance blooms downstream. Other cumulative actions in the area that would reduce the potential for algal growth include implementation of the Klamath River TMDLs (and implementation of TMDLs on Klamath River tributaries) to reduce nutrients, and actions/programs identified in Table 4-3 to reduce sediment input into the Klamath River. Together, the Proposed Action and these cumulative actions would result in beneficial effects by reducing or eliminating conditions supporting blue-green algae. **The Proposed Action's incremental contribution to the significant cumulative effects on phytoplankton would be beneficial for the Hydroelectric Reach and the Klamath River downstream from Iron Gate Dam and the Klamath Estuary.**

4.4.3.1.2 Periphyton

Under the Proposed Action, conversion of the reservoir areas to a free-flowing river and the elimination of hydropower peaking operations could cause long-term increases in nutrient levels and biomass of nuisance periphyton in low-gradient channel margin areas in the Hydroelectric Reach downstream from J.C. Boyle Dam. Periphyton growth in low-gradient channel margin areas in the Hydroelectric Reach could increase on a seasonal basis following dam removal. Removal of the reservoirs and elimination of hydropower peaking operations in the J.C. Boyle Peaking Reach would immediately provide additional low-gradient habitat suitable for periphyton. The particular periphyton species that may become abundant in these areas are unknown.

Periphyton in the Klamath River plays an important role in nutrient dynamics, affecting nutrient fluxes and resulting in short-term changes in dissolved oxygen and pH. Excessive swings in dissolved oxygen and pH can be stressful to aquatic biota, thus too much periphyton can adversely affect water quality and aquatic resources. The growth of nuisance periphyton is therefore considered a significant cumulative effect. The Proposed Action's contribution to this cumulative effect could be substantial. The overall effect of the Proposed Action would likely be to increase periphyton in the re-exposed margins of low gradient river channels in the Hydroelectric Reach until full attainment of the Oregon and California TMDLs can be achieved. **The Proposed Action's incremental contribution to the long-term significant cumulative effect associated with nuisance periphyton growth due to increases in available habitat along channel margin areas of the Hydroelectric Reach downstream from J.C. Boyle Dam would be cumulatively considerable. No feasible mitigation is available to reduce this impact; therefore it remains cumulatively considerable.**

Under the Proposed Action, dam removal and conversion of the reservoir areas to a free-flowing river could cause long-term increases in nutrient levels and biomass of nuisance periphyton in the Klamath River downstream from Iron Gate Dam. Under the Proposed Action, dam removal and conversion of the reservoir areas to a free-flowing river could cause long-term increases in nutrient levels and periphyton biomass in the

Klamath Estuary. Periphyton growth could continue to be relatively high downstream from Iron Gate Dam on a seasonal basis following dam removal because of continuing nutrient inputs from the Upper Klamath Basin, as described for the J.C. Boyle to Iron Gate Dam reach. Periphyton growth in the Klamath Estuary could also be affected by increased nutrient availability following dam removal.

As noted above, periphyton is a significant cumulative effect. The Proposed Action's incremental contribution to the cumulative effect would be minimal. Concentrations of both nutrients are high enough in the river from Iron Gate Dam (RM 190.1) to approximately Seiad Valley (RM 129.4) (and potentially further downstream) that algal growth is nutrient saturated, and nutrients are not likely to be limiting primary productivity (i.e., periphyton growth) in this portion of the Klamath River nitrogen-fixing species currently dominate the periphyton communities in the lower reaches of the Klamath River. Since these species can fix their own nitrogen from the atmosphere, increases in total nitrogen due to dam removal may alter the composition of the periphyton community but it may not substantially increase algal biomass in these reaches because it will be accompanied by only relatively minor increases in total phosphorous. In addition, overall total nitrogen and total phosphorous increases could be less than those predicted by existing models due to implementation of TMDLs and general nutrient reductions in the Klamath Basin. Long-term increase in nutrients in the Klamath Estuary would be relatively small due to the effects of tributary dilution and nutrient retention between Iron Gate Dam and the Estuary.

Because of these many competing factors, some that may favor enhanced periphyton growth downstream from Iron Gate Dam (i.e., increased nutrients transport and recycling), and some that counteract this response (increased uptake and retention of nutrients by periphyton in the Hydroelectric Reach, increased frequency and intensity of scouring events, decreasing nutrient concentrations due to TMDL implementation and KBRA nutrient reduction programs), it is likely that increases in periphyton growth below Iron Gate Dam would be minimal. **The Proposed Action's incremental contribution to the significant cumulative effects associated with long-term periphyton growth in the Klamath River downstream from Iron Gate Dam and in the Klamath Estuary would not be cumulatively considerable.**

4.4.3.1.3 KBRA – Programmatic Measures

Implementation of the Phase I Fisheries Restoration Plan could result in a long-term reduction in nutrients and associated decreases in nuisance and/or noxious phytoplankton and periphyton blooms. Implementation of the Phase II Fisheries Restoration Plan under the KBRA (KBRA Section 10.2) would include a continuation of the same types of resource management actions as under Phase I along with provisions for adaptive management of these actions and would therefore have the same impacts as Phase I. Implementation of Wood River Wetland Restoration could result in reduced nutrient inputs to Upper Klamath Lake and associated decreases in nuisance and/or noxious phytoplankton blooms. Implementation of the Water Use Retirement Program could result in decreases in nutrient inputs to Upper Klamath Lake and associated decreases in nuisance and/or noxious phytoplankton blooms. Implementation of the

Interim Flow and Lake Level Program could result in decreases in nutrient inputs to Upper Klamath Lake and associated decreases in nuisance and/or noxious phytoplankton blooms. Many of these KBRA actions and programs would help to decrease nutrient levels through various measures such as decreasing irrigation and fallowing of cropland leading to a reduction in fertilizer inputs, restoration actions to reduce nutrient inputs to waterways, inundating wetland (peat) soils and creating anaerobic conditions that support nutrient retention, and cattle exclusion fencing in waterways. All these actions to reduce nutrients would help to reduce the prevalence of nuisance and/or noxious phytoplankton blooms. As noted above, phytoplankton and periphyton can adversely affect water quality and wildlife and are considered significant cumulative effects in the Klamath Basin. Other cumulative actions that could also improve nutrients and reduce nuisance and/or noxious phytoplankton and periphyton growth include implementation of the Klamath Basin TMDLs, the elimination of hydropower peaking, periphytic nutrient uptake, and implementation of the KHSA. **The Proposed Action’s incremental contribution to the cumulative effects on nuisance and/or noxious phytoplankton and periphyton blooms in the Klamath Basin would be beneficial. Implementation of the KBRA will require future environmental compliance as appropriate.**

4.4.3.2 Alternatives 3, 4, and 5

Alternative 3 would have similar cumulative effects on nuisance and/or noxious phytoplankton and periphyton growth as the Proposed Action. Alternative 5 would remove two reservoirs; however, two reservoirs would remain and therefore habitat for nuisance and/or noxious phytoplankton would remain and it would have less cumulative benefits than Alternatives 2 and 3. Alternative 4 would not result in any cumulative effects associated with nuisance and/or noxious phytoplankton and periphyton growth. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; therefore there would be no cumulative effects associated with KBRA actions.

4.4.3.3 Mitigation Measures

The Proposed Action’s incremental contribution to the long-term significant cumulative effect associated with nuisance periphyton growth due to increases in available habitat along channel margin areas of the Hydroelectric Reach downstream from J.C. Boyle Dam would be cumulatively considerable. No feasible mitigation is available to reduce this impact; therefore it remains cumulatively considerable.

4.4.4 Terrestrial Resources

The timeframe for cumulative effects on terrestrial resources includes the duration of construction (May 2019 through December 2020), during which temporary impacts would occur, and extends for approximately three years following construction to 2023. Three years was selected as an approximate time during which residual longer term impacts would occur to terrestrial habitat and wildlife from loss of vegetation in construction areas. After three years, some grasses would be expected to regain structure and function with implementation of the planned restoration activities.

Table 4-8 presents a summary of terrestrial resources impacts identified in Chapter 3. These impacts are analyzed for cumulative effects below the table.

Several past, present, and reasonably foreseeable future actions were considered during the cumulative effects analysis (see Table 4-3 and 4-4). Within the area of analysis, past, present and future cumulative actions such as timber harvesting, agriculture, recreation, residential developments, water diversions, and mining, have in the past, or have the potential in the future to adversely affect wildlife and alter habitat. Construction of the KHP and associated facilities has reduced some riparian habitat and may have blocked some wildlife corridors for species travelling along the Klamath River shoreline. Reclamation's Klamath Project and associated infrastructure has reduced and fragmented wetland and riparian habitat. Future developments, such as those proposed in Siskiyou County (see Table 4-4), may also contribute to some loss of habitat or impacts on wildlife species.

There are several cumulative plans and programs in place that seek to conserve terrestrial resources while allowing for certain land use activities. For instance, PacifiCorp's hydroelectric project activities must comply with Biological Opinions issued by the USFWS and NOAA Fisheries Service, and ongoing timber harvest activities must comply with the applicable agency land use plan.

Table 4-8. Summary of Terrestrial Resources Impacts from Chapter 3

Potential Impact	Alternatives	Significance	Mitigation	Significance after Mitigation

4.4.4.1 Alternative 2: Full Facilities Removal of Four Dams

4.4.4.1.1 General Wildlife

Construction activities could result in adverse impacts on wildlife from riparian habitat loss. Some sedimentation from dam removal could decrease riparian habitat temporarily, and this could affect wildlife. Human activity in the Klamath Basin has decreased the abundance of riparian habitat, through development, agricultural activities, timber harvesting, mining, and other activities. Localized disturbance of riparian habitat

downstream due to sedimentation is expected to be short term, with colonization of riparian plant seedlings and subsequent re-vegetation of riparian areas within three years following implementation of the Proposed Action. Additionally, there would be gains in riparian habitat at the reservoirs following dam removal and restoration. **The Proposed Action’s incremental contribution to the cumulative effects on wildlife from loss of riparian habitat would not be cumulatively considerable.**

The Proposed Action could result in impacts on wildlife from the permanent loss of aquatic habitat. The Proposed Action would result in the removal of four reservoirs that provide aquatic habitat for wildlife. No other cumulative actions or projects have been identified that would substantially decrease the amount of open water habitat in the Klamath Basin. **There would be no significant cumulative effects on wildlife from the permanent loss of open water habitat at the reservoirs.**

The Proposed Action could result in impacts on culturally important species. Willows, which are riparian-dependent plants, are culturally important to American Indians who use them for basket-making. Loss of historical wetland and riparian habitat, as noted above, residential development, and agricultural activities such as grazing, have affected the abundance of culturally important plant species such as willows in the Klamath Basin. This loss of culturally important species represents a significant cumulative effect. The Proposed Action’s incremental contribution to this significant effect would be short term and minimal. Riparian habitat is expected to increase in the long term at the reservoirs, and any loss of riparian habitat from sedimentation downstream from the dams is anticipated to be short term in nature. Since willows are one of the first species to re-colonize following disturbance (Riparian Habitat Joint Venture 2009), impacts on these culturally important plants are not anticipated to be significant. **The Proposed Action’s incremental contribution to the significant cumulative effect associated with loss of culturally important species would not be cumulatively considerable.**

The Proposed Action could result in construction-related impacts to terrestrial resources from relocation of the Yreka Water Supply Pipeline, replacement of the water supply pipeline to the Iron Gate Fish Hatchery, and relocation of existing recreation facilities, which would require the construction of new facilities along the river bank. Several actions, including relocation of the Yreka Water Supply Pipeline, the replacement of the water supply pipeline to the Iron Gate Fish Hatchery, and the relocation of existing recreation facilities, could adversely affect terrestrial resources during construction. Other cumulative actions or projects that may also disturb birds include ongoing agricultural activities, mining, road improvements, and new subdivisions approved in Siskiyou County near Iron Gate Dam. Together these actions, considered with past human development, represent significant cumulative effects on terrestrial resources. The Proposed Action’s incremental contribution to the significant cumulative effect could be cumulatively considerable; however, several elements would be incorporated into the project to avoid or reduce adverse impacts on special-status species and common wildlife species, including mitigation measures TER-1 through TER-4. **The Proposed Action’s incremental contribution to the significant cumulative effects on terrestrial resources would not be cumulatively considerable.**

4.4.4.1.2 Birds

Construction activities could result in adverse impacts on birds, including special-status bird species, during construction. The Proposed Action could adversely affect bird species through noise and disturbances from general construction activities. Other cumulative actions or projects that may also disturb birds include ongoing agricultural activities, mining, road improvements, and new subdivisions approved in Siskiyou County near Iron Gate Dam. If these actions occurred during construction in close proximity to the dams, there could be significant cumulative effects on bird species. However, the Proposed Action's contribution to this cumulative effect would be minimal, and specific mitigation (Mitigation Measure TER-2 and TER-3) and other species-specific measures would be incorporated into the project to avoid or minimize impacts to bird species, including protocol level surveys to identify nests, clearing and grubbing

during the non-nesting season, and establishment of buffer zones around nesting bird species. **With these measures, the Proposed Action's incremental contribution to cumulative effects on bird species would not be cumulatively considerable.**

4.4.4.1.3 Amphibians

Construction activities could result in direct mortality or harm to special-status invertebrate, amphibian and reptile species during construction. Construction would require heavy machinery to move through construction areas, staging areas, and haul roads where special-status invertebrate, amphibian and reptile species could occur. The past and present activities in the Klamath Basin such as agriculture, timber harvesting, road construction, and residential developments, considered with future developments noted in Table 4-4, have likely result in significant cumulative effects on amphibians. The Proposed Action's incremental contribution to the significant cumulative effects would not be cumulatively considerable, based on the specific measures have that been incorporated into the project to reduce or minimize impacts on special-status amphibians and reptiles. **The Proposed Action's incremental contribution to the significant cumulative effects on special-status amphibians and reptiles would not be cumulatively considerable.**

Dam removal could result in long-term impacts on amphibians from habitat degradation due to sedimentation in downstream reaches of the Klamath River. Amphibians are highly sensitive to alternations to their aquatic habitats. Sediment inputs in downstream reaches from dam removal would result in filling of riffle substrate necessary for larval phases of amphibian species. The past and present activities in the Klamath Basin such as agriculture, timber harvesting, road construction, and residential developments, combined with the Proposed Action and future developments noted in Table 4-3, could result in significant cumulative effects on amphibians from sedimentation of their habitat. The Proposed Action's contribution to the significant cumulative effects would be minimal. Most sediment is expected to be flushed out during subsequent high flow events (Stillwater 2008), and restoring a more natural sediment regime would be expected to benefit amphibian habitat in the long term. In addition, removal of reservoirs would reduce populations of non-native bullfrogs which prey on native amphibians. **The**

Proposed Action’s incremental contribution to the significant long-term cumulative effects on amphibians from sedimentation would not be cumulatively considerable.

4.4.4.1.4 Bats

The Proposed Action could result in long-term impacts on bats from loss of roosting habitat. Bats have experienced significant cumulative effects associated with the loss of roosting habitat. This has occurred from past and present human activities in the Klamath Basin that have removed tree habitat, such as timber harvesting, agriculture, and road and residential developments. Proposed Action impacts on bats would occur from the loss of dam structures and associated facilities used as roosting habitat. The loss of a bat colony site or adverse effects to an active bat colony under the Proposed Action could contribute to these significant cumulative effects to bats. The Proposed Action’s incremental contribution to the cumulative effect on bats could be cumulatively considerable because bats roost in all four dams or in their associated facilities and structures (FERC 2007) and these would be removed; however, the Proposed Action would provide mitigation for bats (TER-6) that would include bat surveys, exclusion measures, and the replacement of bat roosting structures that would minimize impacts on bats. **The Proposed Action’s incremental contribution to the significant cumulative effects on bats would not be cumulatively considerable.**

4.4.4.1.5 Special-Status Species

Removal of reservoirs could result in impacts on wildlife from the permanent loss of aquatic habitat. The Proposed Action would result in impacts on special-status species from loss of aquatic habitat at reservoirs. Permanent loss of wetland and aquatic habitat at reservoirs would adversely affect wildlife and special-status species populations that use these habitats. No other known actions or projects are expected to substantially reduce the amount of open water habitat available in the Klamath Basin. **There would be no significant cumulative effects on special-status species from the loss of open water habitat.**

4.4.4.1.6 Habitat

Dam removal could result in long-term impacts on riparian habitat from sedimentation in downstream reaches. If the sediment is allowed to move downstream naturally, it is likely that some sedimentation would occur in deep pools or channel margins downstream during low-flow periods and cover wetland/riparian with a veneer of fine material (Bender Rosenthal, Inc. 2011). This short term wetland/riparian habitat alteration would be localized and would not be substantial. However, most sediment is expected to be flushed out during subsequent high flow events (see Section 3.11 Geology, Soils and Geologic Hazards), and restoring a more natural sediment regime would be expected to benefit amphibian habitat in the long term. No other cumulative actions or projects have been identified that would adversely affect riparian habitat in the downstream reaches after during drawdown. **There would be no significant cumulative effects associated with loss of riparian habitat.**

The Proposed Action could result in long-term impacts on wildlife habitat from tree and vegetation removal. During construction, some trees and other vegetation that provides

habitat for birds and other wildlife would be removed at construction areas, upland disposal sites, equipment staging areas, and access and haul roads.

Past, present and future cumulative actions such as timber harvesting, agriculture, recreation, residential developments, water diversions, and mining, have adversely affect wildlife and altered habitat. Construction of the KHP and associated facilities has reduced wildlife habitat. Reclamation's Klamath Project and associated infrastructure has reduced and fragmented wildlife habitat. Future developments, such as those proposed in Siskiyou County (see Table 4-4), may also contribute to some loss of habitat or impacts on wildlife species. Impacts on wildlife habitat are considered significant cumulative effects.

The Proposed Action's incremental contribution to the significant cumulative effects on wildlife habitat would not be cumulatively considerable. Specific measures have been incorporated into the Proposed Action to avoid or reduce impacts on specific bird species, such as bald eagles, if nesting trees are removed during construction. Following construction, restoration of this habitat would be conducted through the planting of native vegetation in accordance with a Habitat Rehabilitation Plan approved by the resource agencies. **The Proposed Action's incremental contribution to the significant cumulative effects on wildlife habitat would not be cumulatively considerable.**

4.4.4.1.7 Plant Species

Construction activities could result in the loss of special-status plants during construction. Construction activities such as the use of vehicles and equipment could result in the loss of special-status plant species. Past, present and future cumulative actions such as timber harvesting, agriculture, recreation, residential developments, water diversions, and mining, have adversely affect wildlife and altered habitat. Construction of the KHP and associated facilities has reduced wildlife habitat. Reclamation's Klamath Project and associated infrastructure has reduced and fragmented wildlife habitat. Future developments, such as those proposed in Siskiyou County (see Table 4-4), may also contribute to some loss of habitat or impacts on wildlife species.

The Proposed Action's incremental contribution to the significant cumulative effects on special-status plants would not be cumulatively considerable. Specific mitigation would be implemented (TER-1 and TER-4) to avoid or reduce impacts on special-status plants, including focused surveys and compensation measures, where necessary. **The Proposed Action's incremental contribution to the significant cumulative effects on special-status plants during construction would not be cumulatively considerable.**

The Proposed Action could result in impacts related to invasive plants. Invasive plants are found throughout the Klamath Basin and have adversely affected agriculture, wildlife, recreation areas, and native plant species. The spread of invasive plants is therefore a significant cumulative effect. The Proposed Action would not have a substantial contribution to this cumulative effect. Measures would be implemented to prevent the introduction of invasive plant species. All construction vehicles and equipment would be cleaned with compressed water or air within a designated containment area to remove

pathogens, invasive plant seeds, or plant parts, which would then be disposed of in an appropriate disposal facility. Implementation of the Reservoir Area Management Plan and the Habitat Rehabilitation Plan would include long-term maintenance and monitoring to control invasive species. Incorporation of these elements into the Proposed Action and implementation of Mitigation Measures TER-1 and TER-4 would avoid or reduce impacts on special-status plants during construction. **The Proposed Action's incremental contribution to the significant cumulative effects associated with the spread of invasive plants would not be cumulatively considerable.**

4.4.4.1.8 Wetlands

Construction of the Proposed Action could result in the loss of wetland and riparian vegetation communities. Dam removal could result in loss of reservoir wetlands.

Disturbances associated with construction areas and haul roads where clearing, grading, and staging of equipment would occur would have impacts on sensitive habitats, including wetlands and riparian vegetation along reservoirs and river reaches.

Under the Proposed Action, there would be unavoidable impacts on wetland habitat at the J.C. Boyle, Copco 1, Copco 2, and Iron Gate Reservoirs (244.5 acres, see Table 3.5-2). However, much of these unavoidable impacts would be temporary, as wetlands would be expected to become reestablished in some areas along the new river channel with adequate hydrology, soils, and vegetation. As these areas would be prone to colonization by invasive plant species, management and control of invasives would occur as part of the Reservoir Area Management Plan and the Habitat Rehabilitation Plan.

A substantial amount of the historical wetlands of the Upper Klamath Basin have been lost to agricultural developments and water diversions (Larson and Brush 2010). As a result, there is less wetland habitat for waterfowl than there was prior to development, but abundant food for dabbling ducks and geese that feed on small grains in fields surrounding the wetlands (Jarvis 2002). Loss of wetland and riparian habitat is therefore a significant cumulative effect.

The Proposed Action's incremental contribution to the cumulative effect associated with loss of wetlands and riparian vegetation would be cumulatively considerable; however, there would also be gains in wetland and riparian habitat following restoration. Based on the Reservoir Area Management Plan, restoration of wetland/riparian habitat would occur at a total of 272 acres following reservoir drawdown. With implementation of the Reservoir Area Management Plan (DOI 2011a), permanent wetland loss at the reservoirs would be reduced. In contrast, wetlands would likely benefit from increased water availability under the Proposed Action, particularly in areas such as the J.C. Boyle bypass reach where water availability is currently limited. If it is determined that wetland losses would be greater than gains, a Compensatory Wetland Mitigation Plan would be developed and implemented in accordance with the requirements of the United States Army Corps of Engineers Section 404 Permit for impacts on Waters of the United States. Implementation of this mitigation (Mitigation Measure TER-5) would reduce the Proposed Action's contribution to the loss of wetland and riparian habitat. **The**

Proposed Action's incremental contribution to the significant cumulative effect associated with loss of wetlands and riparian vegetation would not be cumulatively considerable.

4.4.4.1.9 Wildlife Corridors

The Proposed Action could result in impacts on wildlife corridors. While there is little information on the extent of the loss of wildlife corridors, it is reasonable to assume that past actions such as residential developments, agriculture, timber harvesting, the KHP, and Reclamation's Klamath Project have all contributed to constructing infrastructure that has either blocked wildlife corridors or removed vegetation, causing a significant cumulative effect. The Proposed Action would have a beneficial contribution to this cumulative effect. The Proposed Action would remove the Four Facilities and infrastructure and would re-establish native vegetation at the Klamath River reservoir sites, allowing the establishment of wildlife corridors along the Klamath River. **The Proposed Action's incremental contribution to the significant cumulative effect associated with wildlife corridors would be beneficial.**

4.4.4.1.10 KBRA - Programmatic Measures

Construction activities associated with the Fisheries Restoration Plan- Phase I and Phase II could result in impacts on terrestrial wildlife and/or habitat. The Water Diversion Limitations, On-Project Plan, WURP, and Interim Flow and Lake Level Programs could result in impacts on terrestrial wildlife and/or habitat. Construction activities associated with Fish Entrainment Reduction could result in impacts on terrestrial wildlife and/or habitat. The Fisheries Restoration Plan would include measures to restore riparian and floodplain vegetation throughout the Klamath Basin. While the overall intent of the Fisheries Restoration Plan is to benefit wildlife, there could be some temporary adverse impacts on terrestrial vegetation and wildlife during construction through ground disturbance and the use of construction equipment and vehicles. The WURP program could include juniper removal in order to increase inflow to Upper Klamath Lake. There could be adverse impacts on terrestrial wildlife, including nesting migratory birds, from removal of juniper trees. Fish Entrainment Reduction would entail the installation of fish screens at various water diversion structures for the Klamath Reclamation Project. There could be adverse impacts on riparian vegetation and wildlife habitat within these localized construction areas.

The exact locations for many of the actions planned as part of the KBRA have not yet been identified; therefore, it is difficult to determine what cumulative actions or projects may be occurring that could contribute to cumulative terrestrial wildlife and habitat impacts. However, for the purposes of this analysis, it is assumed that ongoing activities such as timber harvesting, agriculture, livestock grazing, mining, road improvements, and recreation could all be contributing to adverse effects on terrestrial species and could have noise impacts but could also result in adverse changes to habitat or even direct mortality to some species. Therefore, depending on the locations, there could be significant cumulative effects on terrestrial resources. The KBRA's incremental contribution to this significant cumulative effect would be cumulatively considerable. Construction activities and vegetation removal could result in disturbance or mortality to

terrestrial wildlife and habitat. However, mitigation measures would be implemented to reduce or avoid these impacts (TER-1 through TER-4). **The KBRA’s incremental contribution to the significant cumulative effects on terrestrial wildlife and/or habitat would not be cumulatively considerable. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

The Water Diversion Limitations, On-Project Plan, WURP, and Interim Flow and Lake Level Programs could result in impacts on terrestrial wildlife and/or habitat. In general, additional water supply would be expected to increase the numbers of waterfowl using the National Wildlife Refuges. As described in Section 3.15, Socioeconomics, there would be an additional 193,830 waterfowl, with corresponding increases in hunting trips and local revenue. As noted above, there has been a considerable amount of wetland and riparian habitat loss in the Klamath Basin over time, and that has resulted in less wetland habitat for waterfowl than there was prior to development. Impacts on waterfowl and habitat are therefore considered significant cumulative effects. The Proposed Action’s incremental contribution to this cumulative effect would be beneficial as it would increase water supply at the National Wildlife Refuges and would therefore be expected to increase waterfowl habitat and the number of waterfowl visiting the refuges. **The KBRA’s incremental contribution to the cumulative effects on waterfowl and their habitat at the National Wildlife Refuges would be beneficial. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

Modification of aquatic habitat from the Wood River Wetland Restoration project could result in impacts on terrestrial wildlife and/or habitat. Implementation of the Wood River Wetland Restoration may reconnect subsided wetlands adjacent to Agency Lake to provide additional water storage. Therefore, these projects are anticipated to benefit waterfowl, water birds, and other species that utilize wetlands and aquatic habitat through increased reliability of water to wetland habitat. However, some adverse effects could also occur to some species, depending on whether habitats are managed as marsh or open water. There has been a considerable amount of wetland and riparian habitat loss in the Klamath Basin over time, and that has resulted in less wetland habitat for waterfowl than there was prior to development. Impacts on waterfowl and habitat are therefore considered significant cumulative effects. The Proposed Action’s contribution to the significant cumulative effects associated with waterfowl and their habitat would be minimal. The KBRA actions would provide more open water and/or marsh habitat. **The KBRA’s incremental contribution to the cumulative effects on terrestrial wildlife and habitat would not be cumulatively considerable. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

4.4.4.2 Alternatives 3, 4, and 5

Alternative 3 would have similar cumulative effects as Alternative 2 as all dams would be removed. Alternative 4 would involve fish passage facilities and would not result in any cumulative effects as all wildlife impacts would be temporary and minimal; however no

new wildlife corridors would be created. Alternative 5 would have similar cumulative effects to Alternative 2 and 3; however less habitat would be lost during construction and two dam facilities would remain for bat roosting and aquatic habitat. Under Alternative 5, no new wildlife corridors would be created because two dams would still remain in place. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; therefore there would be no cumulative effects associated with KBRA actions.

4.4.4.3 Mitigation Measures

No cumulatively considerable adverse effects related to terrestrial resources would occur; hence, no mitigation measures are required.

4.4.5 Flood Hydrology

Cumulative effects associated with flood hydrology could occur through changes in flows on the Klamath River that could increase the flood risk. The timeline for short-term cumulative effects would be the duration of deconstruction. The timeline for long-term effects after dam removal would be indefinite. Table 4-9 presents a summary of flood hydrology impacts identified in Chapter 3. These impacts are then analyzed for cumulative effects below the table.

Table 4-9. Summary of Flood Hydrology Impacts from Chapter 3

Potential Impacts	Alternatives	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Continued operation of the Klamath Hydroelectric Project and Reclamation’s Klamath Project could alter river flows and result in changes to flood risks.	1	NCFEC	None	NCFEC
Ongoing restoration actions could affect flood hydrology.	1	NCFEC	None	NCFEC
Dam failure could inundate areas in the downstream watershed.	1	LTS	None	LTS
Drawdown of reservoirs could result in short-term increases in downstream surface water flows and could result in changes to flood risk.	2, 3, 5	LTS	None	LTS
Reservoir drawdown and resulting downstream sediment deposition could affect flood risk.	2, 3, 5	LTS	None	LTS

Table 4-9. Summary of Flood Hydrology Impacts from Chapter 3

Potential Impacts	Alternatives	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Changes in flows following dam removal could result in changes to the 100-year floodplain downstream from Iron Gate Dam between River Mile 190 and 171.	2, 3, 5	S	H-1: Emergency Response Plan H-2: Move or Relocate Structures	LTS
Removing the Four Facilities could reduce the risks associated with a dam failure.	2	B	None	B
Removing Copco 1 and Iron Gate Dams could reduce the risks associated with a dam failure	5	B	None	B
Removal of recreation facilities located on the banks of the existing reservoirs which could affect flood hydrology.	2, 3, 5	NCFEC	None	NCFEC
Changes in flows in the Hydroelectric Reach including the J.C. Boyle and Copco 2 Bypass Reaches could affect flood hydrology.	4, 5	LTS	None	LTS
Construction of a new gage within the 100-year floodplain at Copco 2 Dam or J.C. Boyle Dam to measure flows could affect flood hydrology.	5	LTS	None	LTS
Keno Transfer				
Implementation of the Keno Transfer could cause changes to operations affecting flows downstream from Keno Dam, which could cause changes to flood risks.	2, 3	NCFEC	None	NCFEC
East and Westside Facilities – Programmatic Measure				
Decommissioning the East and Westside Facilities could cause changed in flood risk downstream from the facilities.	2, 3	NCFEC	None	NCFEC
Yreka Water Supply Pipeline Relocation – Programmatic Measure				
Removal of Iron Gate Dam would require relocation of the Yreka Water Supply Pipeline which could affect flood risk.	2, 3, 5	NCFEC	None	NCFEC

Physical changes within a watershed produce changes in runoff patterns and associated surface water hydrographs. Historically, the Klamath Basin has experienced a loss of wetland habitat and a conversion to agricultural areas in the upper watershed and along tributaries such as the Scott and Shasta Rivers. The lower watershed remains largely forested, although localized areas of timber harvest and development exist throughout.

In the future, county and city populations in the Klamath Basin are projected to grow throughout the watershed (see Table 4-10). Increases in population would likely spur development of additional housing and businesses to support this growth. Increased development creates additional impervious surfaces, which often channel precipitation into surface water bodies. Most roads and highways in mountainous regions such as the Klamath Basin are located adjacent to streams and rivers. Additionally, some timber harvest would continue into the future; the construction of logging roads to expand timber harvest could also channel sediment and water into surface water bodies. These actions could increase peak flows during storm events.

In addition to increasing populations and new development, climate change may also affect future surface water hydrology. The annual snow packs in the mountain ranges may be reduced, decreasing annual surface water supplies. Storm frequency and severity may increase, causing higher peak flows in rivers and their tributaries during storm events (California Department of Water Resources [CDWR] 2010).

4.4.5.1 Alternative 2: Full Facilities Removal of Four Dams

Drawdown of reservoirs could result in short-term increases in downstream surface water flows and result in changes to flood risks. The Proposed Action would result in short-term increases in flows during reservoir drawdown. Because drawdown would not occur until 2019, population growth and associated increases in development, the creation of new impervious surfaces, and construction of new logging roads or other infrastructure that result in run-off and sediment deposition in waterways could all contribute to changes in peak flows in surface water bodies. Climate change could increase the frequency of large storm events, and could cause more snow melt earlier in the season. These changes have the potential to increase flows on the Klamath River and could result in significant cumulative effects associated with flood risks.

The long-term surface water flow changes associated with future climate change and the Proposed Action’s increase in flows from reservoir drawdown could result in surface water changes such as increased peak flows during storms that could increase the potential flood risks during drawdown. Higher flows may also change the rates and locations of sediment deposition in the channel bed and banks. Flood risk during reservoir drawdown could be a significant cumulative effect.

The Proposed Action’s incremental contribution to the cumulative effect associated with flood risks would be short term and minimal. The reservoir drawdown plans were made with consideration for minimizing flood risks downstream. The Dam Removal Entity (DRE) would carefully control drawdown to maintain flows that would not cause flood risks. Drawing down the reservoirs would increase storage availability in J.C. Boyle, Copco 1, and Iron Gate Reservoirs. If a flood event occurred during drawdown, the DRE would retain flood flows using the newly available storage capacity and continue drawdown after flood risks have ended. Current conditions do not allow these reservoirs to assist in flood prevention in this manner. While the controlled releases during reservoir drawdown would be higher than simulated No Action/No Project Alternative releases during the same time period, they would not be likely to increase flood risks because they would still be within the range of historic flows. **The Proposed Action’s incremental contribution to the short-term cumulative effects on flood risks from reservoir drawdown would not be cumulatively considerable.**

The release of sediment stored behind the dams and resulting downstream sediment deposition under the Proposed Action could result in changes to flood risks.

Sedimentation would occur downstream from the Four Facilities, but the quantity would vary depending on year type. The magnitude of sediment deposition is relatively small compared to sediment loading from other existing sources along the Klamath River. The only measurable sedimentation will occur in the reach from Bogus Creek to Cottonwood Creek. From Willow Creek to Bogus Creek, there is about 1.5 feet of deposition and from Cottonwood to Willow Creeks there is less than 1 foot of deposition. Downstream from Cottonwood Creek, there is less than 0.25 feet of deposition expected. Additionally, the sedimentation will occur in primarily pool and not in the riffle and bedrock sections that tend to control surface elevations. Because the sediment deposition would be small in comparison with the No Action/No Project Alternative, it would not affect stream characteristics in a way that would substantively affect flood inundation or flood risks. Therefore, sediment deposition would have a less than significant effect on flood risk. However, even though its effect was considered less than significant, the increase in bed elevations due to sedimentation was included in the mapping of the 100-yr floodplain inundation areas downstream from Iron Gate Dam described below.

The 100-year floodplain inundation area downstream from Iron Gate Dam could change between River Mile 190 and 171 and result in changes to flood risks. Removal of the Four Facilities under the Proposed Action would change flow patterns and would cause some small changes to the 100 year flood plain. An additional six structures would fall within the current Federal Emergency Management Agency (FEMA) 100-year flood inundation area. In addition, the Proposed Action would release sediment stored behind the dams that could deposit downstream and change the river bed elevation.

While there may be slight changes in surface water elevation from annual variations in precipitation, or ongoing activities in the basin that could change sedimentation in the river channel, there are no projects or actions that have been identified that would substantially change the current flood risk.

4.4.5.1.1 KBRA - Programmatic Measures

Implementation of the Fisheries Restoration Plans could change flows downstream from Upper Klamath Lake, which could result in changes to flood risks. Actions within the floodplain and river channel could generate minor changes in flood risks in and around the specific restoration locations. There are no other known cumulative actions or projects that would change flood risks by placing structures within the floodplain and river channel. Additionally, the restoration actions are designed to improve aquatic and riparian habitat and the potential changes in river hydraulics are intended to improve the habitats' ability to support river fisheries. **There would be no significant cumulative effects associated with changes in flood risk. Implementation of specific plans and projects outlined in the Fisheries Restoration Plans will require the analysis of changes to flood risks in future environmental compliance investigations as appropriate. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

Implementation of Wood River Wetland Restoration by the Bureau of Land Management may change flows upstream and downstream from Upper Klamath Lake, which could result in changes to flood risks. Implementation of Future Storage Opportunities by Reclamation may cause changes to flows upstream and down downstream from Upper Klamath Lake, which could result in changes to flood risks. The KBRA includes a study of Wood River Wetland area management options that could provide additional water storage for a total of 16,000 acre-feet of storage capacity at or adjacent to Agency Lake. Additionally, Reclamation plans to identify and study additional off-stream storage opportunities with a 10,000 acre-feet of storage milestone in implementation of KBRA. Additional storage upstream of Upper Klamath Lake is likely to decrease potential flood risks downstream from Upper Klamath Lake by potentially storing excess flows. No other cumulative actions or projects have been identified that would increase storage capacity and decrease flood risk. **There would be no significant cumulative effects associated with changes to flood risks. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

Implementation of Climate Change Assessment and Adaptive Management may change flows upstream and downstream from Upper Klamath Lake, which could result in changes to flood risks. One of the main purposes of Climate Change Assessment and Adaptive Management would be to respond to and protect basin interests from the adverse affects of climate change. Flood risks could be adversely impacted due to climate changes which increase river flows and/or flooding frequency. Klamath Basin Parties including technical experts would be involved in the development of assessment and adaptive management strategies that would be implemented continuously to respond to predicted climate changes. No other known cumulative actions or projects would help to decrease flood risks from climate change. **There would be no significant cumulative effects associated with flood risks. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

4.4.5.2 Alternatives 3, 4, and 5

Alternative 3 would have similar cumulative flood hydrology effects as Alternative 2. Alternative 5 would involve removal of two dams, with two dams remaining in place and overall cumulative short-term and long-term effects on flood risks would be slightly less than Alternative 2, but changes in the 100-year floodplain would still occur. Alternative 4 would not remove any dams; cumulative flood hydrology effects would be minimal and would be associated with changes in flows to accommodate fish passage facilities. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; therefore there would be no cumulative effects associated with KBRA actions.

4.4.5.3 Mitigation Measures

No cumulatively considerable adverse effects related to flood hydrology would occur; hence, no mitigation measures are required.

4.4.6 Ground Water

Cumulative effects on ground water would occur if other projects or actions in the area of analysis and timeframe would result in changes to ground water levels. The timeframe for the ground water cumulative effects analysis is after 2020 when the dams would be removed, because ground water could be permanently changed. Table 4-11 presents a summary of ground water impacts described in Chapter 3. These impacts are then analyzed for cumulative effects below the table.

Table 4-11. Summary of Ground Water Impacts from Chapter 3

Potential Impact	Alternatives	Significance	Proposed Mitigation	Significance After Mitigation
Continued facility operations could result in impacts on ground water resources.	1, 4	NCFEC	None	NCFEC
Ongoing resource management actions could lead to increased ground water storage.	1, 4, 5	B	None	B
Draining of the reservoirs could lower ground water levels in the aquifer adjacent to the reservoirs, which could impact existing wells.	2, 3, 5	S	GW-1: Deepen or replace affected ground water wells	LTS
Removing the dams and eliminating the reservoirs could reduce ground water discharge to the Klamath River.	2, 3, 5	LTS	None	LTS

Very little information exists on ground water levels in the area directly around the Four Facilities. The ground water wells for which existing data are available (and presented in Section 3.7, Ground Water) are almost all identified as domestic wells. Because of the lack of data, it is not possible to determine if significant cumulative effects have occurred or are presently occurring with respect to ground water levels around the Four Facilities. The only actions identified as potentially affecting ground water levels in the area are the construction of wells as part of past developments, and the potential for construction of new wells for the approved developments in Siskiyou County described in Table 4-4.

4.4.6.1 Alternative 2: Full Facilities Removal of Four Dams

4.4.6.1.1 Ground Water Levels

Under the Proposed Action, ground water levels in existing wells adjacent to the reservoirs could decline in response to the drop in surface water elevation when the reservoirs are removed. The Proposed Action could result in a decline in ground water levels when the reservoirs are removed. Because of the lack of existing data, it is not possible to determine if there are existing significant cumulative ground water effects in the area around the Four Facilities. However, the approved developments noted in Table 4-4 in Siskiyou County around Iron Gate Reservoir, if constructed, may require development of new wells that could cause future declines in ground water levels. This new development, combined with the Proposed Action's declines in ground water levels directly adjacent to the reservoir, could result in a significant cumulative effect associated with declining ground water levels. The Proposed Action's incremental contribution to significant cumulative ground water effects would be cumulatively considerable; however, impacts would be minimized through mitigation measure GW-1, which would deepen or replace all existing wells that experience declining ground water levels as a result of the project. **With this mitigation, the Proposed Action's incremental contribution to any significant cumulative effects associated with a decline in ground water levels in existing wells adjacent to the reservoirs in response to the drop in surface water elevation when the reservoirs are removed would not be cumulatively considerable.**

4.4.6.1.2 Ground Water Recharge

The Proposed Action could cause a reduction in ground water discharge to the Klamath River. Removing the dams and eliminating the reservoirs could result in less percolation of surface water to the underlying ground water aquifer due to removal of the water bodies. Because of the lack of existing data, it is not possible to determine if there are existing significant cumulative effects associated with ground water recharge in the area around the Four Facilities. However, future development near the reservoir sites could, in conjunction with the Proposed Action, contribute to reduced potential for ground water recharge and declines in ground water levels after 2020 through an increase in impermeable surfaces and in increase in ground water use. Overall, a significant cumulative effect associated with declining ground water levels and reduced recharge could occur; however, the Proposed Action's contribution to this cumulative effect would be inconsequential. Current information indicates that the Klamath River reaches in the area of analysis are gaining (i.e., ground water discharges to the stream). Additionally, the Proposed Action would not alter the volume of water that would be flowing through the project area in the Klamath River. The change in ground water recharge would likely be small to negligible because the river would still be present. **The Proposed Action's incremental contribution to significant cumulative effects associated with ground water recharge would not be cumulatively considerable.**

4.4.6.1.3 KBRA - Programmatic Measures

The Water Diversion Limitations program and the On-Project Plan could reduce irrigation water in the driest years, which could increase ground water pumping. Implementation of the On-Project Plan and Water Diversion Limitations program has the

potential to generate significant short-term localized impacts through the increased use of ground water to replace surface water deliveries. It is assumed for the purposes of this analysis that there would be significant cumulative ground water effects because of ground water pumping in response to overall dry conditions. The Proposed Action's incremental contribution to the significant cumulative effects would be cumulatively considerable, but would be minimized through implementation of the Water Diversion Limitations program and On-Project Plan. As discussed in section 3.7.4.3, for Alternative 2, the KBRA would provide more surface water in the driest years. For example, if the KBRA applied in 2010, 145,000 acre feet more surface water would have been available and less ground water pumping would have been required. Also, the On-Project Plan is being developed to include several measures other than ground water pumping to meet water demand. The KBRA also provide increased monitoring and data collection, as well as funding related to ground water management. Moreover, the new USGS ground water model provides resource management agencies a robust tool for maximizing ground water use with the least amount of adverse effects as defined by KBRA, Klamath Water and Power Agency, and resource management agencies. As a result, implementation of the KBRA is expected to slow, halt, or reverse the declining trend in ground water levels over the past decade (i.e. since 2001). **Overall, the KBRA's incremental contribution to the significant cumulative effects on ground water would not be cumulatively considerable. Implementation of the KBRA will require future environmental compliance as appropriate.**

Upland vegetation management under the WURP would increase inflow to Upper Klamath Lake, which could increase ground water recharge. The WURP is intended to permanently increase the flow of water into Upper Klamath Lake by 30,000 acre-feet per year to support restoration of fish populations (KBRA Section 16.2.2). The KBRA action of implementing the WURP would increase ground water recharge and this could have beneficial effect on ground water levels. No other cumulative actions or projects have been identified that would increase ground water recharge in the Klamath Basin. **There would be no significant cumulative effects associated with ground water recharge. Implementation of the KBRA will require future environmental compliance as appropriate.**

The purchase and lease of water under the Interim Flow and Lake Level Program would increase water for fisheries, which could increase reliance on supplies. The Interim Flow and Lake Level Program (KBRA Section 20.4) would be an interim program of water purchase and lease to reduce surface water diversions and further the goals of the fisheries programs during the interim period prior to full implementation of the On-Project Allocation and WURP. This could increase the reliance on ground water sources. It is assumed for the purposes of this analysis that there would be significant cumulative ground water effects in the basin, given continued use of ground water substitution for surface water deliveries curtailed in drought years. The Interim Flow and Lake Level Program's incremental contribution to this cumulative ground water effect would be cumulatively considerable; however, that contribution would be mitigated through, water purchase and lease agreements, with a term greater than the interim period defined in

Section 20.4.2, that would be subject to a consistency requirement with the On-Project Plan. Reduced surface water diversions would not be expected to directly result in increased adverse ground water impacts given provisions developed to prevent impacts to ground water in the KBRA (see Section 15.2.4). With these measures, **the KBRA’s incremental contribution to significant cumulative ground water effects would not be cumulatively considerable. Implementation of the KBRA will require future environmental compliance as appropriate.**

4.4.6.2 Alternatives 3, 4, and 5

Alternative 3 would have similar cumulative ground water effects as those described under Alternative 2, as all dams would be removed. Alternative 4 would not result in any cumulative ground water effects because it would involve construction of fish passage facilities and the dams would remain in place. Alternative 5 could have some similar cumulative ground water effects as Alternative 2; however two dams and associated reservoirs would remain in place. Any changes in ground water levels would likely be less than under Alternative 2, but because the remaining reservoirs would be the smallest of the four, the difference in cumulative ground water effects between Alternative 2 and Alternative 5 would likely be negligible. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; therefore there would be no cumulative effects associated with KBRA actions.

4.4.6.3 Mitigation Measures

No cumulatively considerable adverse effects related to ground water would occur; hence, no mitigation measures are required.

4.4.7 Water Supply/Water Rights

Cumulative effects on water supply and water rights would be associated with changes in Klamath River flow rates as a result of increased demands or diversions from new or existing water supply users. The timeframe for cumulative effects associated with reservoir drawdown impacts is May 2019 through December 2020. The timeframe for long-term cumulative effects is indefinite but would occur after deconstruction is complete (after 2020). Table 4-12 presents a summary of water supply/water rights impacts identified in Chapter 3. These impacts are then analyzed for cumulative effects below the table.

As described in Section 3.8, Water Supply/Water Rights, Oregon is currently undergoing an effort to adjudicate water rights on the Klamath River; this effort will define existing water rights. There are no other known past, present, or future actions or projects that would specifically affect existing water rights on the Klamath River. However, there are several projects described in Section 4.4.5, Flood Hydrology, that have the potential to alter surface water flows, which could affect water supply and the exercise of water rights.

Table 4-12. Summary of Water Rights/Water Supply Impacts from Chapter 3

Potential Impact	Alternatives	Significance	Proposed Mitigation	Significance After Mitigation
Continued operation of the Four Facilities could affect water supply operations.	1, 4	NCFEC	None	NCFEC
Ongoing restoration actions would continue to be implemented and could affect water supply availability.	1	NCFEC	None	NCFEC
Removal of various recreation facilities located on the banks of the existing reservoirs which could affect water supply or water rights.	2, 3, 5	NCFEC	None	NCFEC
Flow changes downstream from Iron Gate Dam could affect water supply downstream from Seiad Valley.	2, 3, 5	LTS	None	LTS
Changes in flow downstream from Iron Gate Dam could affect water rights holders.	2, 3, 5	LTS	None	LTS

4.4.7.1 Alternative 2: Full Facilities Removal of Four Dams

Dam removal could change surface water flows available for diversion downstream from Iron Gate Dam. Dam removal could cause changes in water supply compared to the No Action/No Project Alternative. Modeling results show that the Proposed Action would change flows downstream from Iron Gate Dam, and this could affect water diversions and existing water rights. The modeling considers KBRA actions in addition to dam removal.

Water supply in the Klamath Basin has been affected by the construction of Reclamation's Klamath Project, the KHP, variations in annual precipitation throughout the Klamath Basin, drought, and regulatory requirements such as the recommendations in the Biological Opinions for Reclamation's Klamath Project and the KHP that contain specific stream flow requirements. Water demands for industries such as agricultural, timber harvesting, and mining also affect water supply. Changes in water supply therefore represent significant cumulative effects in the Klamath Basin.

The Proposed Action's contribution to this cumulative effect would be minimal. The modeling results showed either a slightly higher or slightly lower flow rate on the Klamath River downstream from Iron Gate Dam. These differences would diminish farther downstream from Iron Gate Dam. The modeling results show that at Seiad Valley, approximately 62 miles downstream from the Iron Gate Dam, the flow rates would have almost no change.

The Proposed Action would change the flows in the river downstream from Iron Gate Dam, but the flows available in the river would still be substantially greater than the peak diversion. The most conservative comparison is just downstream from Iron Gate Dam, where the flows would be the lowest in the potentially affected reach. Comparing the

peak potential diversion with low flow conditions, the diversions would be approximately 16 percent of the Klamath River flows during a dry year². The flow rate of 824 cfs is the seasonal low during the month of July, when irrigation and livestock demands are the greatest. Because the amount of flow diverted for water right users between Iron Gate Dam and Seiad Valley would be less than 20 percent of the flow in the Klamath River in the upstream portions of this reach during dry year, low flow conditions, water right users are not likely to experience decreased supplies because of the changes in flows. **The Proposed Action's incremental contribution to the significant cumulative effect on water supply and water rights would not be cumulatively considerable.**

Release of stored sediment during drawdown of reservoirs could change Klamath River geomorphology and affect water intake pumps downstream from Iron Gate Dam. The release of sediment from the drawdown of the reservoirs could affect downstream water intake systems. Individual downstream intake facilities could be inundated with sediment deposits, causing operational problems.

Other cumulative actions that may increase sediment and could affect downstream water intake pumps include transportation improvement project identified in Table 4-4 for Siskiyou County, new subdivisions near Iron Gate Dam in Siskiyou County, and other proposed developments. Other more general projects and activities that are not easily identifiable but likely to occur, such as timber harvesting, mining, and agriculture, livestock grazing, and road-related erosion could also contribute to cumulative effects associated with sediment. Climate change could also affect sediment by increasing the number of heavy precipitation events each year.

Increased sediment in the Klamath River could result in significant cumulative effects on downstream water intake pumps. The Proposed Action's contribution to the significant cumulative impacts on water intake pumps from increased sediment would be cumulatively considerable; however, mitigation measure WRWS-1 would mitigate that contribution. The subject measure would provide for an investigation of potentially affected intake and pump sites at the request of the water user. If effects on water supply intakes occur as a result of dam removal, the DRE will complete modifications to intake points as necessary to reduce effects to a less-than-significant level. **With implementation of this mitigation, the Proposed Action's incremental contribution to the cumulative effects on water intake pumps from sedimentation associated with reservoir drawdown would not be cumulatively considerable.**

Activities associated with IMs could result in changes to PacifiCorp's water rights. Prior to construction, IM 16 (Water Diversions) would eliminate three screened diversions from Shovel and Negro Creeks and would seek to modify PacifiCorp's water rights to

² The increase during July and August is an average based on reported values on Statement Diversion and Use forms available on California Electronic Water Rights Information Management System for the Klamath River.

move the points of diversion to the mainstem Klamath River. As discussed above, water supply in the Klamath Basin has been adversely affected over time, and changes in water supply represent significant cumulative effects.

The Proposed Action's contribution to this cumulative effect through implementation of IMs would be minimal. While this measure would require a change to PacifiCorp's water rights, it would not affect the exercise of the water right (i.e., the quantity of water diversions) or flow in the Klamath River. **Therefore, the Proposed Action's incremental contribution to the significant cumulative effect on water supply and water rights would not be cumulatively considerable.**

4.4.7.1.1 KBRA - Programmatic Measures

Implementation of the trap and haul element of the Fisheries Reintroduction and Management Plan could require water rights to divert water for the fish handling facilities. Fish handling facilities to collect fish downstream from Keno Dam and at Link River Dam would require water sources. The facilities would not consumptively use the water; the water would pass through the facilities for release back into the system. Trap and haul is likely to be an exempt use under ORS 537.141(d) and OAR 340-0010(2)(c)(B) if it causes no injury to existing water rights and if it is found to be not harmful to fish or wildlife after consultation with Oregon Department of Fish and Wildlife. The geographic separation between this project and the hydroelectric facility removal actions analyzed above eliminate any potential for negative water supply effects generated by this program from contributing to water supply effects generated by facility removal. **The trap and haul element of the Fisheries Reintroduction and Management Plan would not contribute to the significant cumulative effects on water supply would not be cumulatively considerable. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

Implementation of the Wood River Wetland Restoration Project would result in changes to water storage opportunities at Agency Lake, which could affect water supply. The study of additional off-stream storage opportunities in the Upper Klamath Basin to identify new storage opportunities could affect water supply. A study of Wood River Wetland area management options would investigate the potential for providing additional water storage for a total of 16,000 acre-feet of storage capacity at or adjacent to Agency Lake. Additionally, Reclamation plans to identify and study additional off-stream storage opportunities. KBRA parties would support ongoing investigations and acquisition of additional storage. This additional storage would improve water supply reliability and assist with alleviating short-term impacts related to water supply delivery during Water Diversion Limitations (another KBRA program) helping to offset a portion of the deficiencies. No other cumulative actions or projects have been identified that would increase storage on the Klamath River. **There would be no significant cumulative effects on water supply from changes in water storage. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

Implementation of Water Diversion Limitations to Reclamation's Klamath Project could result in changes to water diversions, which may affect the exercise of certain water rights and water supply. Water Diversion Limitations provide specific allocation of water for refuges and limitations on specific diversions for the Reclamation's Klamath Project intended to increase water availability for fisheries purposes. While reducing diversions during the driest years would affect water supply for irrigation, it would not affect what is needed for public health and safety. Water may not be available to fulfill some water rights or adjudication claims during dry years; however, the On-Project Plan, Drought Plan, and Future Storage Opportunities to be implemented as part of the KBRA would help to offset a portion of these deficiencies. No other cumulative actions or projects have been identified that would change water diversions and affect water rights and water supply. **There would be no significant cumulative effects associated with water supply and water rights. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

Implementation of the On-Project Plan to allow for full implementation of Water Diversion Limitations to Reclamation's Klamath Project would result in changes to water diversions for irrigation in dry years, which could affect the exercise of certain water rights or adjudicated rights. The purpose of the On-Project Plan is to provide additional water supply or reduce the demand for Reclamation's Klamath Project to make up the differences between anticipated use and actual diversion. These actions include: land fallowing and shifting to dryland crop alternatives, efficiency and conservation measures (i.e. drip irrigation), development of ground water sources, or creation of additional storage. No other cumulative actions or projects have been identified that would affect water supply and water rights. **There would be no significant cumulative impacts associated with water supply and water rights. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

Implementation of the WURP increases instream flow to Upper Klamath Lake which could affect water rights and water supply upstream of Upper Klamath Lake. The WURP is a voluntary program for the purpose of supporting fish populations restoration by permanently increasing inflow to Upper Klamath Lake by 30,000 acre-feet per year. Some measures include implementing water efficiency projects, increasing natural storage through wetland or improved riparian area performance, and purchase and retirement of water rights from willing sellers. This could affect water rights, although retirement of water rights would be voluntary. No other cumulative actions or projects have been identified that would result in the purchase or retirement of water rights from willing sellers. **The KBRA's incremental contribution to the significant cumulative effects on water supply would be beneficial. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

Implementation of Off-Project Water Settlement (OPWAS) negotiations could affect the exercise of certain water rights and adjudicated rights upstream of Upper Klamath Lake. The intent of OPWAS is to negotiate a settlement of long-standing water disputes

between the Upper Klamath Water Users Association, Klamath Tribes, the Bureau of Indian Affairs, and potentially other water users in the Upper Basin. The negotiated settlements would resolve certain contests to significant major water right claims in the Upper Klamath Basin. Implementation of OPWAS would be a beneficial effect to resolve water rights and adjudicated rights and a less than significant impact to unresolved cases due to reciprocal assurances. There are no other cumulative actions or projects that have been identified that would resolve certain contests to major water rights claims that could affect water supply/water rights. **The KBRA’s incremental contribution to the significant cumulative effects on water supply and water rights would be beneficial. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

Implementation of Off-Project Reliance Program could change water deliveries for irrigation upstream of Upper Klamath Lake to Off-Project water users, affecting the water supply. The agreement establishes a program to avoid or mitigate the immediate effects of unexpected circumstances affecting water availability for irrigation in the Off-Project area. Activities under the Off-Project Reliance Program may include: funding water leasing to increase water supply availability for irrigation in the Upper Klamath Basin or mitigating the economic impacts of lost agricultural production by Off-Project irrigators. The program is intended to provide additional water availability and help minimize reductions in water supply. No other cumulative actions or projects have been identified that would substantially change water supply availability. **The KBRA’s incremental contribution to the significant cumulative effects on water supply and water rights would be beneficial. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

Implementation of Drought Plan water and resource management actions could result in changes to water supply deliveries for Klamath Basin interests during drought years. Implementation of an Emergency Response Plan could result in a change to water supply deliveries in the event of failure to a facility in Reclamation’s Klamath Project or dike on Upper Klamath Lake or Lake Ewauna. Implementation of Climate Change Assessment and Adaptive Management could result in changes to water deliveries depending on climatic changes. The Drought Plan would improve short-term water supply reliability during drought by releasing stored water, paid forbearance agreements, conservation, ground water substitution, or ground water sharing. The Emergency Response Plan would prepare water managers for an emergency affecting the storage and delivery of water needed for KBRA implementation. The Climate Change Assessment and Adaptive Management program would respond to and protect basin interests from the adverse affects of climate change by improving storage capabilities during the wet years and conservation during dry years. Implementation of these programs would be beneficial to water supply because they would help to reduce the effects of drought, climate change, and emergencies by increasing water supplies and/or improving water supply reliability. No other known cumulative actions or plans would increase water supply reliability or water supply during drought, climate change, or emergency situations. **The KBRA’s incremental contribution to the significant cumulative effects on water supply and**

water rights would be beneficial. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.

Implementation of Interim Flow and Lake Program during the interim period could change water deliveries affecting water supply. The goal of the Interim Flow and Lake Level Program is to “further the goals of the Fisheries Program” through an interim program of water purchases and leases during the interim period prior to full implementation of the On-Project Plan and WURP. Leases and purchases of water under this interim program shall be from willing sellers and counted towards instream water supply. No other known cumulative actions or projects would result in the purchase or lease of water during the interim period. **The KBRA’s incremental contribution to the significant cumulative effects on water supply and water rights would be beneficial. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

Implementation of KBRA Section 15.3 Water Rights Assurances Related to Tribal Water Rights could affect tribal trust water rights and water supply. KBRA Section 15.3 and related provisions provide certain assurances related to Reclamation’s Klamath Project operations in Oregon and directly tie into claims filed as part of the Oregon adjudication. The only tribal water rights being litigated there involve claims filed by the United States and the Klamath Tribes, not to any other Indian tribe in the Klamath Basin. Under the KBRA, these claims--to Upper Klamath Lake (Case 286 in the Oregon adjudication) and to the Klamath River from the Lake to the Oregon border (Case 282)--will be subordinated in relation to the Reclamation’s Klamath Project as specified in the KBRA. In particular, Section 15.3.9 (the KBRA “no-call” provision) affects the ability of the United States or other parties to alter Reclamation’s Klamath Project water budget in the future if the Secretary of the Interior were to make an Affirmative Determination regarding dam removal, the KBRA were implemented, dams were removed, and certain KBRA conditions were met.

Significant cumulative effects associated with water supply have occurred in the past, as described above. Therefore, tribal trust water rights and water supply represent a significant cumulative effect. However, overall, restoration would be consistent with any trust obligation to all Basin tribes, including those who currently oppose the KBRA and its authorizing legislation. Conversely, litigation or adjudication of these and other issues entails considerable risks and costs, takes years if not decades to resolve, and ultimately does not provide the opportunity, both in programs and appropriations, that the KBRA and related activities will if enacted. In fact, the Oregon adjudication originated in the mid-1970s, begun in earnest in the mid-1990s, and has yet to complete the first of two major phases. Implementation of KBRA Section 15.3 Assurances Related to Tribal Water Rights would be beneficial to water rights and water supply. **The Proposed Action’s incremental contribution to the cumulative effects on tribal trust water rights and water supply would not be cumulatively considerable.**

4.4.7.2 Alternatives 3, 4, and 5

Alternatives 3 and 5 would have similar cumulative water supply and water rights impacts as described for Alternative 2 because both alternatives would involve dam removal. Alternatives 4 and 5 would require implementation of a trap and haul measure which would be functionally equivalent to the KBRA’s trap and haul element of the Fisheries Reintroduction and Management. For the reasons discussed above for the KBRA’s trap and haul element of the Fisheries Reintroduction and Management, the trap and haul measure for Alternatives 4 and 5 would also have a less than significant impact on water rights and water supply. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; therefore there would be no cumulative effects associated with KBRA actions.

4.4.7.3 Mitigation Measures

No cumulatively considerable adverse effects related to water supply and water rights would occur; hence, no mitigation measures are required.

4.4.8 Air Quality

Cumulative air quality effects occur when a variety of projects or sources contribute to emissions in the area of analysis. The timeframe for air quality impacts associated with deconstruction would be the length of the deconstruction/construction period. Deconstruction and construction activities would occur from May 2019 through December 2020 for Alternatives 2, 3, and 5. Table 4-13 presents a summary of air quality impacts described in Chapter 3. These impacts are analyzed for cumulative effects below the table.

Table 4-13. Summary of Air Quality Impacts from Chapter 3

Potential Impact	Alternatives	Significance	Proposed Mitigation	Significance After Mitigation
Vehicle exhaust and fugitive dust emissions from dam removal activities and construction of fish passage could increase emissions of VOC, NOx, CO, SO ₂ , PM ₁₀ , and PM _{2.5} to levels that could exceed Siskiyou County's thresholds of significance.	2, 3, 5	S	AQ-1: MY 2015 or newer engines for offroad construction equipment AQ-2: MY 2000 or newer engines for on-road construction equipment AQ-3: MY 2010 or newer engines for haul trucks AQ-4: Dust control measures during blasting operations	S

- N/A = Not Applicable

4.4.8.1 Alternative 2: Full Facilities Removal of Four Dams

Vehicle exhaust and fugitive dust emissions from dam removal activities could increase emissions of volatile organic carbon (VOC), nitrogen oxides (NO_x), carbon monoxide (CO), sulfur dioxide (SO₂), inhalable particulate matter < 10 microns (PM₁₀), and fine particulate matter < 2.5 microns (PM_{2.5}) to levels that could exceed Siskiyou County's thresholds of significance. Under the Proposed Action, total emissions of NO_x, PM₁₀, and PM_{2.5} exceed the significance criteria for the Four Facilities. The greatest source of NO_x emissions from each of the dams would be off-road construction equipment, followed by on-road trucks, and then employee commuting vehicles. The major sources of PM₁₀ and PM_{2.5} emissions would be fugitive dust from unpaved roads and then cut/fill activities. Secondary formation of PM_{2.5} could also occur from NO_x and sulfur oxide (SO_x) emissions; however, these pollutants are not emitted in sufficient quantities to affect the Klamath Falls Nonattainment Area. Any adverse impacts would be temporary.

The population in the affected counties is expected to increase in the future. Increases in population and housing could increase traffic, utility demands, and construction projects, which could all result in increased air pollution. Additionally, air pollutant emissions

associated with past and present development and activities have contributed to local and regional air pollution. As a result, the air quality emissions in the region create significant cumulative air quality effects. Dam removal would have an incremental contribution to the cumulative effect that would be cumulatively considerable. Dam removal would result in substantial, albeit temporary emissions, of construction-related air pollutants (i.e., equipment emissions and fugitive dust) and resultant air quality impacts near the project sites. Even with all feasible mitigation measures (AQ-1 through AQ-4), the Proposed Action would cause a substantial air quality impact associated with PM₁₀ emissions because it would exceed Siskiyou County Air Pollution Control District Rule 6.1 permitting criteria. The Proposed Action's contribution to the cumulative effect would be significant. No additional feasible mitigation is available to adequately reduce project-related impacts below the criteria. **The incremental contribution to the significant cumulative effect on air quality from dam removal would be cumulatively considerable. No other feasible mitigation is available to reduce PM₁₀ emissions; therefore, they remain cumulatively considerable.**

Construction of a new, elevated Yreka Water Supply Pipeline and steel pipeline bridge to support the pipe above the river could result in short-term and temporary increases in criteria pollutant emissions from vehicle exhaust and fugitive dust that could exceed Siskiyou County's thresholds of significance. Although criteria pollutant emissions are expected to be less than significant for the construction of the Yreka Water Supply Pipeline, air pollutant emissions associated with past and present development have contributed to local air pollution. As a result, the air quality emissions in the region are considered significant cumulative effects. The contribution to the significant cumulative air quality effect from construction of the water supply pipeline would not be cumulatively considerable. As shown in Table 3.9-4, the pipeline is expected to result in some air quality emissions from the use of equipment; however, the emissions would not exceed the significance criteria. No long-term effects air quality effects would occur. **The incremental contribution to significant cumulative air quality effects from construction of Yreka's Water Supply Pipeline would not be cumulatively considerable.**

Activities associated with several IMs could result in short-term and temporary increases in criteria pollutants from vehicle exhaust and fugitive dust that could exceed Siskiyou County's thresholds of significance. As discussed above, air pollutant emissions associated with past and present development and activities have contributed to local and regional air pollution; therefore, air quality emissions are considered significant cumulative effects. IMs would be implemented prior to facilities removal; therefore, they would not contribute to the emissions from those activities. IMs 7 and 16 would result in a small increase in emissions associated with construction vehicles, haul trucks, and construction workers. However, based on the limited amount of construction equipment expected to be used simultaneously, peak daily emissions are not expected to exceed the significance criteria described previously and would not result in long-term effects. **The incremental contribution to significant air quality effects from implementation of IMs would not be cumulatively considerable.**

Restoration actions could result in short-term and temporary increases in criteria pollutant emissions from vehicle exhaust and fugitive dust from the use of helicopters, trucks, and barges. As discussed above, air pollutant emissions associated with past and present development and activities have contributed to local and regional air pollution. As a result, the air quality emissions in the region are considered significant cumulative effects. Restoring the reservoir areas would not result in cumulatively considerable impacts. Restoration actions would result in temporary emissions, of construction-related air pollutants (i.e., equipment emissions and fugitive dust) but they would not exceed significance criteria (See Table 3.9-5). **The restoration actions' incremental contribution to the significant cumulative effect on air quality would not be cumulatively considerable.**

Demolition and reconstruction of various recreation facilities could result in short-term and temporary increases in criteria pollutant emissions from vehicle exhaust and fugitive dust. Air pollutant emissions associated with past and present development have contributed to local air pollution. As a result, the air quality emissions in the region are considered significant cumulative effects. Demolition and reconstruction of recreation facilities would result in contributions to the cumulative effect that would not be cumulatively considerable. On- and off-road construction equipment would be used to complete these activities, which would occur after the Facilities removal actions. Based on the number of recreation facilities that would be reconstructed or demolished, it is assumed that emissions would not exceed existing significance criteria (See Table 3.9-6). **The incremental contribution to the significant cumulative effect on air quality from relocation and demolition of recreation facilities would not be cumulatively considerable.**

Fugitive dust emissions from demolition activities could impair visibility in Federal Class I areas. Dam demolition activities would create fugitive dust and could temporarily impair visibility. No other known cumulative actions or projects would substantially increase dust and impair visibility during reservoir demolition because most of the area would be closed to outside traffic and restricted to construction worker use for safety concerns. There would be no significant cumulative fugitive dust effects that could impair visibility.

Decommissioning the East and Westside Facilities could cause adverse air quality effects. Decommissioning of the East and Westside canals and hydropower facilities of the Link River Dam by PacifiCorp as a part of the KHSA would eliminate the need to divert at Link River Dam into the two canals. Air quality emissions in the region are considered significant cumulative effects. However, incremental contribution of the decommissioning of the East and Westside Facilities to the significant cumulative effects would be minimal. These construction activities would be conducted in the years prior to Facilities Removal and would not overlap with other construction or demolition activities. Peak daily emissions would likely be minimal and are not expected to exceed the significance criteria. The incremental contribution to the significant cumulative effect on air quality from the East and Westside Facilities decommissioning would not be cumulatively considerable.

4.4.8.1.1 KBRA - Programmatic Measures

Construction activities associated with the KBRA programs could result in temporary increases in air quality pollutant emissions from vehicle exhaust and fugitive dust. Activities associated with the implementation of the Fisheries Reintroduction and Management Plan could result in temporary increases in air quality pollutant emissions from vehicle exhaust associated with trap and haul activities. Potential construction activities include channel construction, mechanical thinning of trees, road decommissioning, fish passage and facilities construction, breaching levees, and fish hauling. Several of these activities would require construction equipment with the potential to emit air quality pollutants. As noted above, the air quality emissions in the region are considered significant cumulative effects. Due to the potentially large amount of construction activities that would occur for the various KBRA programs, it is anticipated that the KBRA's incremental contribution to the significant cumulative air quality effects would be cumulatively considerable. Mitigation Measures AQ-1, 2, and 3 would be implemented to reduce these effects. **With mitigation, the KBRA's incremental contribution to the cumulative effects on air quality would not be cumulatively considerable; however, emissions from any construction actions completed in the same year as Facility Removal actions may remain cumulatively considerable even with all feasible mitigation. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

4.4.8.2 Alternatives 3, 4, and 5

Alternatives 3 and 5 would have similar cumulative effects to the Proposed Action as both of these alternatives would exceed existing criteria and would cause cumulatively considerable air quality impacts during construction. Alternative 4 would have less cumulative effects because no Facilities would be removed. Alternative 4 would not result in cumulatively considerable impacts from construction emissions. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; **therefore, there would be no cumulative effects associated with KBRA actions.**

4.4.8.3 Mitigation Measures

The Proposed Action, Alternative 3, and Alternative 5 would have cumulatively considerable impacts associated with construction emissions, even with implementation of all feasible mitigation. No other feasible mitigation is available to reduce these emissions; **therefore, the cumulative effects associated with on- and off-road construction equipment would remain cumulatively considerable for Alternatives 2, 3, and 5.**

4.4.9 Greenhouse Gases/Global Climate Change

By its very nature, climate change is a cumulative impact from various global sources of activities that incrementally contribute to global GHG concentrations. Individual projects provide a small addition to total concentrations, but contribute cumulatively to a global phenomenon. The goal of California Assembly Bill (AB) 32 and Oregon House Bill

3543 both require GHG emission reductions from existing conditions. As a result, cumulative GHG and climate change impacts must be analyzed from the perspective of whether they would impede each State’s ability to meet its emission reduction goals. While it is not necessary to show zero or negative GHG emission impacts, the project must show a reduction in emissions from business-as-usual. The timeframe for short-term deconstruction/construction related effects is the duration of construction. The timeframe for the power replacement is indefinite as this would be a permanent change. Table 4-14 presents a summary of GHG/climate change impacts identified in Chapter 3. These impacts are then analyzed for cumulative effects below the table.

Table 4-14. Summary of Greenhouse Gases/Global Climate Change Impacts from Chapter 3

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA

**4.4.9.1 Alternative 2: Full Facilities Removal of Four Dams
Effects of the Proposed Action on Climate Change**

Vehicle exhaust from dam removal activities could increase GHG emissions in the short term to levels that could exceed the significance criteria. Under the Proposed Action, there would be a net increase in GHG emissions from deconstruction of the facilities; however, these emissions would be temporary and would not contribute to long-term emissions. Construction related activities associated with decommissioning of the dams would contribute 8,558 MTCO_{2e} to California’s GHG emission for one year⁴. Amortizing these construction emissions over thirty years results in approximately 285 MTCO_{2e} per year, well below the 10,000 MTCO_{2e} threshold. Moreover, even without amortizing construction emissions over thirty years such emissions are 1,442 MTCO_{2e} below the threshold. The 1990 GHG emissions level (and so the 2020 emissions target ascribed by AB 32) is 427 million metric tons of CO_{2e} (MMTCO_{2e}).

The emissions from dam removal would be 0.002 percent of the target emissions. In 1990, GHG emissions from construction were 0.67 MMTCO_{2e}; therefore, the Proposed Action would equal approximately 1 percent of allowable construction emissions.

⁴ The value of 8,558 MTCO_{2e} includes emissions from the J.C. Boyle Dam. Although J.C. Boyle Dam is located in Oregon, GHG emissions related to J.C. Boyle Dam could affect California because climate change is a global phenomenon. Therefore, and for purposes of full disclosure, emissions related to J.C. Boyle Dam are being analyzed under CEQA.

Climate change by nature is a result of cumulative emissions of GHG on a global scale. Worldwide, California⁵ is the twelfth to sixteenth largest emitter of CO₂, and is responsible for approximately two percent of the world's CO₂ emissions (California Energy Commission [CEC] 2006). As shown in Figure 3.10-1, transportation is responsible for 37 percent of the State's GHG emissions, followed by electricity generation (24 percent), the industrial sector (19 percent), commercial and residential (9 percent), agriculture and forestry (6 percent) and other sources (5 percent). It is reasonable to expect that these sectors would continue to contribute to GHG emissions in the future. Climate change therefore represents a significant cumulative effect for the entire State and could have a variety of meteorological and hydrologic implications, described in Section 3.10.4.1, Greenhouse Gases/Global Climate Change.

The Proposed Action would generate GHG emissions only for the duration of construction; no long-term GHG emissions would be produced. Because emissions would represent 1 percent of allowable construction emissions at the 1990 level, **the incremental contribution to the significant cumulative effect on climate change from deconstruction would not be cumulatively considerable.**

Activities associated with several IMs could result in short-term and temporary increases in GHG emissions from vehicle exhaust. Restoration actions could result in short-term and temporary increases in GHG emissions from the use of helicopters, trucks, and barges. Relocation and demolition of various recreation facilities could result in short-term and temporary increases in GHG emissions from vehicle exhaust. Before deconstruction activities begin, IMs 7 and 16 would involve vehicle traffic that would temporarily increase GHG emissions. Following drawdown of the reservoirs, revegetation efforts would be initiated using helicopters, trucks, and barges that would produce emissions. Some recreation facilities would be relocated or demolished. These activities would produce GHG emissions and could contribute to climate change.

As noted above, climate change represents a significant cumulative effect for the entire State and could have a variety of meteorological and hydrologic implications, described in Section 3.10.4.1, Greenhouse Gases/Global Climate Change. Restoration actions and relocation or demolition of recreation facilities would have a minimal incremental contribution to significant cumulative climate change effects. Since dam demolition activities would be less than significant, and the scale of emissions expected from the IMs is expected to be substantially less than dam removal, it is likely that emissions from implementation of the IMs would also not exceed the significance criteria. For restoration actions, as shown in Table 3.10-5, total GHG emissions would not exceed 704 MTCO_{2e} per year. Furthermore, the addition of new grassland and other vegetation would sequester CO₂ emissions in the long term, but the sequestered CO₂ would likely not offset all of the emissions occurring during restoration on an annual basis. Annual GHG emissions for relocation and demolition of various recreation facilities were

⁵ Although the area of analysis for the project is restricted to portions of northern California and southern Oregon, GHG emissions data is not available at this level of detail; therefore, background emissions data (i.e., existing conditions) is presented at the State level for both California and Oregon.

estimated using information provided in the Detailed Plan for Dam Removal – Klamath River Dams (Reclamation 2012) and CalEEMod, Version 2011.1.1. Approximately 160 MTCO_{2e} would be emitted during relocation and demolition of the recreation facilities. Since dam demolition activities would be less than significant and changes to the recreation facilities would not overlap, emissions from these activities would also not exceed the significance criteria. **The incremental contribution to the significant cumulative effects associated with GHG emissions from implementation of IMs, restoration actions, and recreation facility relocation or demolition would not be cumulatively considerable.**

4.4.9.1.1 Power Replacement

Removing a renewable source of power by removing the dams could result in increased GHG emissions from possible non-renewable alternate sources of power. As described above, climate change from GHG emissions represents a significant cumulative effect for the State. The emissions generated from power replacement would be permanent. The possible increase that may result from replacing the dam facilities with higher emitting power producing facilities would account for three percent of the expected emissions reduction. Under a business-as-usual scenario, which assumes that the Scoping Plan would not be implemented, this would impede California's ability to meet its emission reduction goal. The Proposed Action's incremental contribution to cumulative effects on climate change would be cumulatively considerable. Mitigation Measures CC-1 through CC-3 would be implemented to reduce emissions from power replacement. While these measures would lessen emissions, **the incremental contribution to the significant cumulative effect associated with GHG emissions and climate change from power replacement would remain cumulatively considerable until PacifiCorp adds new sources of renewable power that would replace the removed dams.**

Decommissioning the East and Westside Facilities could cause short-term and temporary increases in GHG emissions. Decommissioning of the East and Westside canals and hydropower facilities of the Link River Dam by PacifiCorp as a part of the KHSA would stop diversions of water flows at Link River Dam into the two canals, back into the Link River. Construction equipment used in the decommissioning action would be substantially less than the equipment required to complete dam demolition activities and the decommissioning action would be conducted in the years prior to 2020.

As described above, climate change from GHG emissions represents a significant cumulative effect for the State. Since dam demolition activities would be less than significant, it is likely that emissions from the decommissioning action would also not exceed the significance criteria. **The incremental contribution to the significant cumulative effect associated with GHG emissions and climate change from the East and Westside Facility Decommissioning would not be cumulatively considerable.**

4.4.9.1.2 KBRA - Programmatic Measures

Construction activities associated with the KBRA could cause temporary increases in GHG emissions and climate change. Operational activities associated with the Fisheries Reintroduction and Management Plan could result in temporary increases in GHG

emissions from vehicle exhaust associated with trap-and-haul activities. Several KBRA programs may cause some GHG emission impacts from the use of vehicles and heavy equipment. As described above, climate change from GHG emissions represents a significant cumulative effect for the State. The KBRA's incremental contribution to GHG emissions and climate change would be minimal and short term. Sufficient information is not currently available to quantify emissions; however, the quantity of equipment required to complete these activities is expected to be less than that required to complete the dam removal activities. Emissions are not expected to exceed the South Coast Air Quality Management District (SCAQMD)'s threshold of significance for industrial emissions (10,000 MTCO_{2e} per year), especially when amortized over thirty years. **The incremental contribution to significant cumulative effects associated with GHG emissions and climate change from KBRA construction activities would not be cumulatively considerable. Implementation of the KBRA will require future environmental compliance as appropriate.**

Implementation of the Power for Water Management Program of the KBRA could create new renewable energy sources which would provide affordable electricity to allow efficient use, distribution, and management of water. Implementation of the Drought Plan and the Climate Change Assessment and Adaptive Management Plan could affect climate change-related impacts. KBRA actions could involve the development of renewable energy sources, which would provide green energy. The Drought Plan would identify water and resource management actions to minimize risk associated with drought, which is a projected climate change impact for the Klamath Basin and the Pacific Northwest. The Climate Change Assessment and Adaptive Management Plan includes early and frequent assessment of the existing and future impacts of climate change. Together, these actions and programs would have beneficial effects associated with climate change. One other project, the Klamath Falls Bioenergy Facility, is in the early stages of planning but has issued a Notice of Intent to file an application from the Oregon Department of Energy (ODE) (see Table 4-4). This facility would burn wood waste and would produce up to 38.5 megawatts (MW) of electrical power. Together these actions would result in beneficial cumulative effects on climate change by providing electricity produced by renewable resources. **The incremental contribution to the significant cumulative effects associated with climate change and GHG from the Power for Water Management Program, the Drought Plan, and the Climate Change Assessment and Adaptive Management Plan would be beneficial. Implementation of the KBRA will require future environmental compliance as appropriate.**

4.4.9.2 Alternatives 3, 4, and 5

Alternative 3 would have similar cumulative effects to the Proposed Action as all Four Facilities would be removed. Alternative 5 would have similar construction related cumulative effects to the Proposed Action, although there would be less of a contribution to the cumulative GHG impacts because there would be less overall emissions as only two dams would be removed. Alternative 4 would have construction-related emissions but they would be less than Alternatives 2 and 3 because Alternative 4 would involve

fish passage facility construction rather than dam removal. The Proposed Action, Alternative 3, Alternative 4, and Alternative 5 would have cumulatively considerable impacts associated with the loss of hydropower and the replacement of the power with alternate sources. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; therefore there would be no cumulative effects associated with KBRA actions.

4.4.9.3 Mitigation Measures

The loss of hydropower and the possible replacement of that power with another energy source would have cumulatively considerable impacts associated with GHG emissions and climate change. No additional feasible mitigation is available to reduce these emissions; therefore, the impact remains cumulatively considerable for Alternatives 2, 3, 4, and 5.

4.4.10 Geology, Soils and Geologic Hazards

Cumulative effects on geology, soils, and geologic hazards would be associated with erosion and sedimentation downstream from Iron Gate Dam. The timeframe for the cumulative effects analysis includes the duration of construction and continues up to ten years afterwards (the expected duration for sand in the bed to return to equilibrium levels between Willow Creek and Cottonwood Creek).

Table 4-15 lists the impacts and mitigation presented in Chapter 3. These impacts are analyzed for cumulative effects below the table.

Table 4-15. Summary of Geology, Soils and Geologic Hazards Impacts from Chapter 3

Potential Impact	Alternatives	Significance	Proposed Mitigation	Significance After Mitigation
Continued impoundment of water in the reservoirs could continue to trap sediment at rates similar to historical rates.	1, 4	NCFEC	None	NCFEC
Continued impoundment of water in the reservoirs could continue to prevent access to the diatomite beds at Copco 1 Reservoir.	1, 4	NCFEC	None	NCFEC
Draining of the reservoirs could uncover diatomite beds at Copco 1 Reservoir; however the land would be transferred to a State agency which would not allow commercial use, access to the mineral resource would not be changed.	2, 3, 5	NCFEC	None	NCFEC

Table 4-15. Summary of Geology, Soils and Geologic Hazards Impacts from Chapter 3

Potential Impact	Alternatives	Significance	Proposed Mitigation	Significance After Mitigation
Construction and deconstruction activities could change erosion patterns through heavy vehicle use, excavation, and grading which could result in soil erosion.	2, 3, 4, 5	LTS	None	LTS
Draining of the reservoirs could cause instability along the banks of the reservoirs	2, 3, 5	LTS	None	LTS
Draining of Copco 1 Reservoir could eliminate wave induced erosion thereby improving stability for upland hillsides and reducing the potential for erosion.	2, 3, 5	LTS	None	LTS
Draining of the reservoirs could cause river bank erosion downstream.	2, 3, 5	LTS	None	LTS
Draining of the reservoirs could result in short-term increases in sedimentation in slow-moving eddies and pools downstream from the reservoirs to the Klamath River estuary.	2, 3, 5	LTS	None	LTS
Draining of the reservoirs could result in changes to seismic or volcanic activity.	2, 3, 5	LTS	None	LTS
Draining of the reservoirs could result in long-term changes in the amount of erosion of the exposed reservoir bottom sediment remaining in the river channel.	2, 3, 5	LTS	None	LTS
Draining of the reservoirs could result in long-term changes to downstream sediment deposition from the erosion of remaining reservoir sediments.	2, 3, 5	LTS	None	LTS
Draining of the reservoirs could leave sediments that would dry out and could affect restoration activities and/or future road construction activities.	2, 3, 5	S	GEO-1: Geotechnical analysis of the site	LTS
Dam removal activities would include the removal of various recreation facilities which could affect geology and soils.	2, 3, 5	NCFEC	None	NCFEC
Keno Transfer				
The Keno Transfer could have adverse effects to geology, soils, or geologic hazards.	2, 3	NCFEC	None	NCFEC

Table 4-15. Summary of Geology, Soils and Geologic Hazards Impacts from Chapter 3

Potential Impact	Alternatives	Significance	Proposed Mitigation	Significance After Mitigation
East and Westside Facilities – Programmatic Measure				
The decommissioning of the East and Westside Facilities could have adverse effects to geology, soils, or geologic hazards.	2, 3	NCFEC	None	NCFEC
Yreka Water Supply Pipeline Relocation – Programmatic Measure				
Removal of Iron Gate Dam would require relocation of the Yreka Water Supply Pipeline which could affect geology and soils.	2, 3,5	NCFEC	None	NCFEC
Klamath Basin Restoration Agreement – Programmatic Measures				
Implementation of the Phase I Fisheries Restoration Plan could result in construction related sediment erosion.	2, 3	LTS (short term)/ B (long term)	None	LTS/B

The major past actions that have affected geology, soils, and geologic hazards in the area of analysis are the construction of the KHP and Reclamation’s Klamath Project. These actions have permanently altered the natural erosion and deposition processes of the Klamath River, increased the potential for landslides and erosion in some areas, and restricted access to mineral resources through the presence of the reservoirs. These actions continue to affect geology, soils, and geologic hazards today. Past actions that have increased soil erosion or altered soils include timber harvesting, urban development, agriculture, and mining. Actions potentially benefitting soil erosion include soil erosion control measures required by the Five Counties Road Maintenance Program, and the Northwest Forest Plan, as well as existing water quality and stormwater regulations (CWA Section 401, and 402, TMDLs). In the future, proposed new subdivisions identified in Table 4-3 could increase soil erosion; however, they are expected to adhere to existing regulations and implement measures to minimize soil erosion and stormwater runoff.

4.4.10.1 Alternative 2: Full Facilities Removal of Four Dams

4.4.10.1.1 Soil Erosion and Sedimentation during Deconstruction

Soil disturbance associated with heavy vehicle use, excavation, and grading could result in erosion during removal activities. Drawdown of reservoirs could cause bank erosion downstream. Drawdown of reservoirs and release of sediment would result in short-term increases in sedimentation in slow-moving eddies and pools downstream from the reservoirs and in the Klamath River estuary. Soil erosion has increased in the past due to human activity and has altered the Klamath River's banks. Increased sedimentation in the Klamath River has also adversely affect water quality and aquatic species. Other cumulative actions and projects that could contribute to soil erosion and sedimentation in the river include road improvement projects, new subdivisions, and other future developments. Other more general projects and activities that are likely to occur, such as timber harvesting, mining, agriculture, livestock grazing, and road-related erosion could also contribute to cumulative effects associated with sediment. Soil erosion and sedimentation represent significant cumulative effects.

Because soil disturbance from heavy vehicle use, excavation, and grading could result in erosion during deconstruction activities, the Proposed Action's incremental contribution to the cumulative effect associated with soil erosion would be cumulatively considerable; however, mitigation would be implemented to minimize these impacts. The Proposed Action would obtain coverage under the General Stormwater National Pollution Discharge Elimination System Permit (NPDES) for Construction Activities in both Oregon and California would be required as per Section 402 of the CWA. Coverage under this permit requires the development and implementation of an Erosion and Sediment Control Plan prior to deconstruction that describes BMPs to prevent erosion. Implementation of these BMPs would minimize the potential for erosion into the reservoir areas and would reduce the Proposed Action's contribution to the cumulative effect. Inasmuch as the requirements of the General Stormwater NPDES Permit for Construction Activities apply to all new construction, such BMPs would also be implemented in other projects, thereby reducing overall cumulative effects.

Drawdown of the Four Facilities would occur simultaneously beginning in January 2020, but is not expected to substantially increase soil erosion through landslides or declining water levels. Although some landslides and erosive areas have been identified in the lower river, based on the expected flow rates that are similar to existing flow rates, substantial amounts of additional erosion are not expected to occur downstream from any of the dams as a result of reservoir drawdown. The proposed drawdown rates are consistent with the historic discharge rates from the reservoirs and would be adjusted depending on the water year; therefore, flow rates downstream from the dams are not anticipated to increase substantially above median historic rates, if at all (discharges from the reservoirs would be similar to seasonal 10-year flood flows from the reservoirs). Additionally, existing erosion at Copco 1 Reservoir is largely the result of wave action, and emptying the reservoir would remove the source of shoreline erosion and future landslides and would ultimately result in improved stability for the upland hillsides and existing development.

During reservoir drawdown in 2020, the sediment behind the four dams would be released downstream. Since all reservoirs would be drawn down concurrently, sediment released from the upstream reservoirs would remain suspended and is not anticipated to settle within Iron Gate Reservoir. However, the released sediment would likely exceed the carrying capacity of the river during some water year types, and would result in sedimentation and particle settling downstream in eddies, pools, and the Klamath River estuary. Any settling or sedimentation of fine sediment in eddies or pools is expected to be minimal and short-lived. Little settling or sedimentation is expected to occur in the Klamath River estuary, particularly due to the location of its sandbar offshore (rather than within the mouth itself). Overall, the release of sediment downstream during reservoir drawdown would not exceed the existing sediment load added by any tributary, and as such the transport capacity of the river may be sufficient to transport the additional load, particularly since the river is supply-limited in regards to fine-grained material and sand. **The Proposed Action's incremental contribution to the short-term significant cumulative effects associated with soil erosion and sedimentation from deconstruction activities and reservoir drawdown would not be cumulatively considerable.**

4.4.10.1.2 Bank Stability and Landslides

Drawdown of the four reservoirs could cause instability along the banks of the reservoirs. Reservoir drawdown at Copco 1 would reduce the potential for erosion and future landslides. No large-scale landslides are anticipated in newly exposed areas during drawdown. In the long term with implementation of reservoir restoration actions including hydro seeding, landslides and erosion would not be expected at a higher frequency or of a larger size than what is currently contributed from the slopes currently adjacent to the reservoirs. Because existing erosion at Copco 1 Reservoir is largely the result of wave action, emptying the reservoir would remove this source of shoreline erosion. No other cumulative actions or projects would substantially change the stability of the banks or the potential for landslides during reservoir drawdown. **There would be no significant cumulative effects associated with bank stability and landslides during reservoir drawdown.**

4.4.10.1.3 Seismic Activity

Drawdown of reservoirs could result in changes to seismic or volcanic activity. Reservoir drawdown is not expected to result in substantial changes in seismic or volcanic activity in the area of analysis. No other known actions or projects in the area of analysis would have the potential to change the seismic or volcanic risk in the area of analysis. **There would be no significant cumulative effects.**

4.4.10.1.4 Soil Erosion and Sediment Deposition after Dam Removal

Following dam removal, reservoir sediment remaining could result in changes in the amount of erosion in the river channel. Following dam removal, reservoir sediments remaining could result in changes to downstream sediment deposition. As noted above, soil erosion and sediment deposition have adversely affected the Klamath River and are considered significant cumulative effects. The Proposed Action's contribution to these cumulative effects would be short term and minimal.

After dam removal, approximately 36 to 57 percent of sediment would be eroded, depending on the water year type. The remaining sediment would remain on the reservoir terraces and dry. Minimal erosion is expected following completion of reservoir drawdown and dam removal activities.

After it is dry, the remaining sediment would be unlikely to erode downstream except during storm and other high-flow events. As previously discussed, the Klamath River is supply-limited for fine-grained material. Further, based on the estimated settling velocity of the remaining sediment and average flows during wet years and storm events, it is expected that any eroded sediment would be transported as suspended sediment flushed downstream. There would be minimal erosion and sediment deposition from the remaining sediments after dam removal.

Additionally, many of the ongoing programs such as the TMDLs, the Hoopa Valley Tribe Water Quality Control Plan (Hoopa Valley Indian Reservation 2008), the Water Quality Control Plan by the Yurok Tribe (2004) and the Draft Eco-Cultural Resources Management Plan (2010) by the Karuk Tribe that contain measures and programs to improve water quality, various watershed and creek restoration projects by the Hoopa Valley Tribe and Siskiyou County noted in Table 4-4, the Northwest Forest Plan, and the Five Counties Road Maintenance Program may actually reduce soil erosion and sediment deposition in the Klamath River, and help to reduce the overall cumulative effect. **The Proposed Action's incremental contribution to the significant cumulative effect associated with erosion and downstream sediment deposition after reservoir drawdown would not be cumulatively considerable.**

4.4.10.1.5 Unstable Soils

Following dam removal, the reservoir sediment remaining would dry and could affect restoration activities and/or future road construction activities. After dam removal, an estimated 43 to 64 percent of the sediment in the reservoirs would remain and settle on the terraces of the new river channel. Initial sampling conducted on the sediment indicates that once dry, it has a tendency to crack and substantially decrease in porosity. This characteristic could limit future construction activities (e.g., access road construction, recreation facilities). No other known actions or projects would change the amount of unstable soils in the area of analysis. Additionally, implementation of mitigation measure GEO-1 would reduce potential impacts of the Proposed Action by requiring a geotechnical analysis to determine suitability for any planned developments. **No significant cumulative effects associated with unstable soils would occur.**

4.4.10.1.6 KBRA - Programmatic Measures

Implementation of the Phase I and Phase II Fisheries Restoration Plans could result in construction related sediment erosion. Construction actions including the operation of construction equipment and the associated soil disturbance could result in erosion into the active river channel and could cause new or exacerbate existing landslide areas. Additionally gravel augmentation could result in temporary sediment transport and deposition downstream from the construction site.

Soil erosion has increased in the past due to human activity and has altered the Klamath River's banks. Increased sedimentation in the Klamath River has also adversely affect water quality and aquatic species. Other cumulative actions and projects that could contribute to soil erosion and sedimentation in the river include road improvement projects, new subdivisions, and other future developments. Other more general projects and activities that are likely to occur, such as timber harvesting, mining, agriculture, livestock grazing, and road-related erosion could also contribute to cumulative effects associated with sediment. There are also several ongoing programs such as implementation of the Klamath Basin TMDLs, the Hoopa Valley Tribe Water Quality Control Plan (Hoopa Valley Indian Reservation 2008), the Water Quality Control Plan by the Yurok Tribe (2004) and the Draft Eco-Cultural Resources Management Plan (2010) by the Karuk Tribe, various watershed and creek restoration projects by the Hoopa Valley Tribe and Siskiyou County noted in Table 4-4, the Northwest Forest Plan, and the Five Counties Road Maintenance Program may actually reduce soil erosion and sediment deposition in the Klamath River.

The KBRA's contribution to the significant cumulative effects associated with soil erosion and landslides would be cumulatively considerable; however, BMPs would be implemented to minimize these impacts. Given these BMPs (see Appendix B), the short-term effects on sediment erosion and landslides would be reduced. Moreover, in the long-term implementation of the Phase I and II Fisheries Restoration Plans would be expected to generate a beneficial reduction in sediment erosion through improved river channel stability, and generate no change from existing conditions for landslides. **The KBRA's incremental contribution to cumulative effects on soil erosion and landslides would not be cumulatively considerable. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

4.4.10.2 Alternatives 3, 4, and 5

Alternative 3 would have similar cumulative effects to the Proposed Action as all Four Facilities would be removed. Alternative 4 could have some erosion during construction, but would not involve reservoir drawdown or dam removal and would therefore contribute to fewer cumulative effects. Alternative 5 would have similar effects to those described for the Proposed Action; however, two dams would remain in place so less sediment would be released and less deconstruction would occur. This would reduce the amount of soil erosion and sedimentation. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; therefore there would be no cumulative effects associated with KBRA actions.

4.4.10.3 Mitigation Measures

No cumulatively considerable adverse effects related to geology, soils and geologic hazards would occur; hence, no mitigation measures are required.

4.4.11 Tribal Trust

A large number of past, present, and future actions have contributed to cumulative effects associated with Tribal Trusts. The timeframe for cumulative effects includes the duration of construction (May 2019 through December 2020), during which temporary impacts would occur, and extends indefinitely following construction for long-term effects associated with restoration of the Klamath River fisheries.

Several past, present, and future actions were considered during the cumulative effects analysis, including those identified by the tribes as having the greatest cumulative potential to adversely impact Tribal Trust Assets: hydroelectric energy production, mining, timber extraction, agricultural production, and cattle grazing. These actions have resulted in poor water quality, a decline in fisheries, and decline in culturally important plants and animals, and have affected tribal health, economies, cultural practices and traditional ceremonies. Impacts on Tribal Trust Assets from some of these land uses, particularly mining and timber extraction, have decreased in the last few decades due to better land management practices. In addition, restoration projects, including those being carried out by the tribes themselves, have mitigated some of these impacts. However, the KHP significantly affects the trust resources of the Klamath Basin tribes and, by extension, their cultural values. Therefore, this evaluation was based on the potential for the project alternatives to result in cumulative effects on Tribal Trust Assets when considered along with the past, present, and future activities.

4.4.11.1 **Alternative 2: Full Facilities Removal of Four Dams**

To the federally recognized Tribes in the Klamath Basin, the KHP dams and associated reservoirs, along with other actions identified above, represent a significant cumulative adverse effect on Tribal Trust Assets. Removal of the four dams under the Proposed Action would result in long-term benefits to Tribal Trust Assets through the restoration of salmon fisheries and traditional fishing sites, improved water quality, and restored riparian habitats that support culturally important plants and animals. The restoration of salmon fisheries would create an opportunity for tribal members to improve their diet , allow for cultural practices and traditional ceremonies to continue, and could provide a source of income for Tribes that participate in a commercial fishery.. Water quality, including temperature and toxic algal blooms, would improve with removal of the dams, benefitting culturally important plants and animals and allowing traditional practices and ceremonies that require bathing to resume. **Together, the Proposed Action’s benefits, along with ongoing fisheries restoration and water quality actions identified in Table 4-4, and better mining and timber extraction land management practices, would result in cumulative benefits to Tribal Trust Assets.**

4.4.11.1.1 **KBRA - Programmatic Measures**

Implementation of the Tribal Fisheries and Conservation Management Program could result in impacts/effects to Trust Resources and other traditionally used resources. Implementation of the Mazama Forest Project could result in impacts/effects to Trust Resources and other traditionally used resources. Implementation of the Tribal Fisheries and Conservation Management Program would provide funding to assist the Klamath

Basin tribes in developing their capacity to participate in resource management activities within the basin, particularly relating to tribal fishing and revitalization of tribal subsistence and other economic activities. Actions associated with the Mazama Forest Project would help The Klamath Tribes gain back culturally important lands and become more economically self-reliant. The other main cumulative action that would benefit the Klamath Basin tribes would be the implementation of the KHSAs and removal of the Four Facilities. This would help to restore fisheries and improve water quality. Other actions that would also contribute benefits include the implementation of the Klamath Basin TMDLs to improve water quality, various restoration projects noted in Table 4-4 above, and the Northwest Forest Plan, the Trinity River Restoration Program, and the Five Counties Road Maintenance Program which contain provisions for improving water quality and enhancing fisheries on the Klamath River. Together these would provide substantial cumulative benefits to the Klamath Basin tribes. **The KBRA's incremental contribution to the significant cumulative effects on Trust Resources and other traditionally used resources would be beneficial. Implementation of specific plans and projects associated with the KBRA will require future environmental compliance as appropriate.**

4.4.11.2 Alternatives 3, 4, and 5

Alternative 3 would result in cumulatively beneficial effects on Tribal Trust Assets similar to those described for Alternative 2. Alternative 5 would also result in some cumulative benefits, although these would be less than Alternative 2 and 3 because two dams would remain in place and could block some fish passage and would not substantially improve water quality conditions. Alternative 4 would have little cumulative benefits because water quality issues associated with the reservoirs would remain. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; therefore there would be no cumulative effects associated with KBRA actions.

4.4.11.3 Mitigation Measures

No cumulatively considerable adverse effects related to Tribal Trust Assets would occur; hence, no mitigation measures are required.

4.4.12 Cultural and Historic Resources

Cumulative effects would result from the loss or degradation of important historic and cultural resources in the Klamath Basin.

Table 4-16 lists the impacts and mitigation presented in Chapter 3. These impacts are analyzed for cumulative effects below the table.

Table 4-16. Summary of Cultural and Historic Resources Impacts from Chapter 3

Table 4-4 presents the projects that were considered in the analysis, including the KHP, road improvements, and future proposed subdivisions around Iron Gate Dam. In addition to these projects, past, present, and future county, municipal, and private development in the region surrounding the reservoirs is also considered in this analysis.

4.4.12.1 Alternative 2: Full Facilities Removal of Four Dams

The Proposed Action would result in direct effects to J.C. Boyle Dam, Copco 1 Dam, Copco 2 Dam, and Iron Gate Dam, their associated hydroelectric facilities, and on the Klamath Hydroelectric Historic District (KHHD) considered eligible for inclusion on the National Register and California Register. The Four Facilities contribute to the KHHD, which is presumed eligible for inclusion on the National Register and on the California Register. Removal of the four dams and all associated facilities would adversely affect each dam's eligibility and the overall integrity of the KHHD because a large portion of this district would be removed.

The Proposed Action would result in adverse effects on an important and unique cultural resource. There are very few of these types of facilities in existence today. Other actions that are likely to occur and could adversely affect the KHHD include additions to buildings, replacement of equipment, internal reconfiguration of buildings, demolition of structures, or lack of maintenance of facilities. Adverse impacts on the KHHD would be considered significant regional and Statewide cumulative effects.

The Proposed Action's incremental contribution to the significant cumulative effects on the KHHD would be cumulatively considerable. The Proposed Action would remove the Four Facilities, eliminating a large portion of the district. Mitigation measure CHR-1 through CHR-4 would be implemented to reduce the impacts; however, even with this mitigation the incremental contribution to the significant cumulative effects would remain cumulatively considerable. No additional feasible mitigation is available to reduce these cumulative impacts. **The Proposed Action's incremental contribution to the significant cumulative effect on the KHHD would remain cumulatively considerable even with all feasible mitigation.**

Reservoir drawdown and construction activities, including use of haul roads and disposal sites for demolition debris, could affect archaeological and historic sites, Traditional Cultural Properties (TCPs), and cultural landscapes that are eligible for inclusion on the National Register and/or California Register and possibly Native American human remains. Installation of the Yreka Water Supply Pipeline could affect archaeological and historic sites that are eligible for inclusion on the National Register or California Register. Construction activities including use of haul roads and disposal sites for demolition debris under the Proposed Action could affect/impact archaeological and historic sites, TCPs, and cultural landscapes that are eligible for inclusion on the National Register or California Register. Removal of the recreational facilities after reservoir drawdown may affect archaeological or historic sites that could be eligible for inclusion on the National Register or California Register or human remains.

Archaeological and historic sites, TCPs, and cultural landscapes in the vicinity of the Four Facilities and have been adversely affected through human activity, development, and construction of the KHP. Historically, the displacement of Indian Tribes by Euroamericans led to the loss of their traditional lands and culture. Economic pursuits such as mining, logging, ranching, and farming further contributed to these impacts. The construction of towns, roads, and other developments over time have likely disturbed or altered many sites in the area. The KHP, constructed in phases from 1918 through 1962,

brought power to region and has been recommended as eligible for inclusion on the National Register as the KHHD under criterion a for its association with the industrial and economic development of southern Oregon and northern California. However, the creation of the reservoirs has likely inundated some cultural sites and the build-up of sediment behind the reservoirs may have buried some of these sites. Artificial water fluctuations from the reservoirs have resulted in erosion along the lower terraces. Cultural resources have been impacted by these changing water levels. Known impacts include exposing cultural materials to the public, sometimes leading to illegal excavation of these sites. At least one site is known to have exposed human remains from these circumstances. Actions by a Federal agency resulted in the reburial of the exposed remains and temporary stabilization of the river bank. Therefore, significant cumulative effects have occurred to archaeological and historic sites, TCPs, and cultural landscapes within the Area of Potential Effect.

The Proposed Action's incremental contribution to the cumulative effects on archaeological and historic sites, TCPs, and cultural landscapes would be cumulatively considerable. The dam removal and reservoir drawdown could affect 32 known sites located along the current shores of the reservoirs, ten ethnographic village sites, an unknown number of sites that may be submerged in the reservoirs and human remains that may be isolated or associated with those sites. Also, several hundred sites along and near the Klamath River downstream from the dams and reservoirs may be exposed or damaged from temporary increase in flows during reservoir drawdowns. Associated riverscape sites could be adversely affected through erosion, exposure, and vandalism. Increased flows along the Klamath River could undercut, erode, or flood sites along or near the banks of the river, also affecting contributing elements of the riverscape. Drawdown of the reservoirs and the flushing of sediment would likely expose submerged sites around and under the reservoirs. After reservoir drawdown, any cultural sites that become exposed could be damaged through vandalism or natural processes, especially if they occur in areas proposed for public recreation.

Modifications of the proposed haul roads and use of disposal sites could affect/impact sites (including 17 sites previously identified during earlier survey coverage of the roads) that are located along the haul roads and/or at the disposal sites. In addition, the location of disposal sites at features associated with construction of the dams may contribute to the KHHD and be historic properties/historical resources.

The existing water supply pipeline for the City of Yreka passes under Iron Gate Reservoir and would have to be relocated. The pipeline itself may be a historic property or historical resource and would need to be evaluated for eligibility. Ground disturbance could result in the discovery of historic and/or archaeologically significant sites. The construction of footing to support the pipe bridge could uncover previously unknown sites.

Recreation facilities, such as campgrounds and boat ramps, currently located along the reservoir banks will need to be relocated down slope to be near the new river bed once the reservoir is removed. These facilities are not eligible for the National Register or

California Register, and were not known to impact archaeological sites when they were built. Additional ground disturbance from removal of these facilities may affect/impact previously unidentified historic properties/historical resources.

The Proposed Action's incremental contribution to the significant cumulative effects on cultural resources would be reduced through mitigation. Additional cultural resources surveys and monitoring of the drawdown zone would be conducted as land is exposed. Avoidance, minimization, and mitigation measures would be implemented, as appropriate. A cultural resources management plan would be developed, through consultations, to manage and protect endangered and exposed cultural resources. Mitigation measures CHR-1 through CHR-4 would be implemented to minimize or avoid impacts to these resources. **The Proposed Action's incremental contribution to the significant cumulative effect on archaeological and historic sites, TCPs, and cultural landscapes would not be cumulatively considerable.**

The decommissioning of the East and Westside Facilities could have adverse effects on historic resources or historic properties. Decommissioning of the East and Westside canals and hydropower facilities of the Link River Dam by PacifiCorp as a part of the KHSA will stop diversion of water flows at Link River Dam into the two canals, back in to Link River. Following decommissioning of the facilities there will be no change in outflow from Upper Klamath Lake or inflow into Lake Ewauna. As described above, significant cumulative effects have occurred to archaeological and historic sites, TCPs, and cultural landscapes within the Area of Potential Effect. The Proposed Action's incremental contribution to the significant cumulative effects would be minimal. Decommissioning does not typically involve deconstruction of the facilities. Instead, buildings and equipment that are too large to easily remove or are fixed in place are usually fenced to prevent entry. **The Proposed Action's incremental contribution to the significant cumulative effect on archaeological and historic sites, TCPs, and cultural landscapes would not be cumulatively considerable.**

4.4.12.1.1 KBRA - Programmatic Measures

Implementation of the KBRA actions could result in impacts to archaeological and historic sites, TCPs, and cultural landscapes that are eligible for inclusion on the National Register and/or California Register and possibly Indian human remains. Implementation of the KBRA could result in river restoration actions, ground disturbing activities, or forest management practices that could have a significant impact on cultural and historic resources that are eligible for inclusion on the National Register and/or California Register.

Given the past and present significant cumulative effects on cultural resources in the area, as described above for the Proposed Action, it is assumed that the KBRA's incremental contribution to cumulative effects on cultural resources would be cumulatively considerable; however, mitigation measures, including CHR-2, CHR-3, and CHR-4, as appropriate, would be implemented to reduce such contribution. **With mitigation, the KBRA's incremental contribution to significant cumulative effects on historic properties, historical resources, human remains, or archaeological and historic sites**

would not reduce these effects to a less than significant level; therefore, they would be cumulatively considerable. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.

4.4.12.2 Alternatives 3, 4, and 5

All alternatives would have cumulatively considerable impacts on the KHHD. Alternatives 3 would have similar cumulative cultural resources effects as described for Alternative 2. Alternative 4 would not require relocation of the Yreka pipeline and would not contribute to cumulative effects associated with the pipeline relocation. Alternative 4 would likely affect a smaller overall area during construction and would therefore decrease the potential for disturbing previously unknown resources. Alternative 5 would leave two dams and reservoirs in place, and would expose less area that may contain cultural resources. Alternative 5 would likely require less overall general construction, roads, and ground disturbance than Alternatives 2 and 3; therefore it could result in fewer impacts to previously unknown resources. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; therefore there would be no cumulative effects associated with KBRA actions.

4.4.12.3 Mitigation Measures

While there would be cumulatively considerable impacts on the KHHD under Alternatives 2, 3, 4, and 5 even with mitigation, no additional feasible mitigation is available to substantially reduce or avoid these cumulative effects. They would remain cumulatively considerable.

4.4.13 Land Use, Agricultural and Forest Resources

Cumulative effects on land use, agriculture, and forest resources would be associated with changes in existing zoning, or conversion of agriculture and forest lands to non-agriculture and non-forest lands. The timeframe for agricultural and forest resources includes the duration of deconstruction (May 2019 through December 2020). Table 4-17 lists a summary of land use, agriculture, and forest resources impacts presented in Chapter 3. These impacts are then analyzed for cumulative effects below the table.

While there are many different past, present, and potentially future cumulative activities that could affect land use, such as agriculture, timber harvesting, mining, and new subdivisions planned in Siskiyou County, there are no cumulative activities that have been identified that would specifically conflict with existing land use plans or zoning, or result in a conversion of agricultural lands to non-agricultural uses or forest lands to non-forest uses.

Table 4-17. Summary of Land Use, Agricultural and Forest Resources Impacts from Chapter 3

Potential Impact	Alternatives	Significance	Proposed Mitigation	Significance After Mitigation
The continued operation of and impoundment of water at the Four Facilities could conflict with applicable land use plans, policies, or regulations adopted for the purpose of avoiding or mitigating an environmental effect.	1	NCFEC	None	NCFEC
The exposure of the currently inundated lands from the removal of the Four Facilities could conflict with applicable land use plans, policies, or regulations adopted for the purpose of avoiding or mitigating an environmental effect.	2, 3	NCFEC	None	NCFEC
The construction of fish passage at the Four Facilities, or the construction activities associated with the removal of Copco 1 and Iron Gate dams and the construction of fish passage at J.C. Boyle and Copco 2 could conflict with applicable land use plans, policies, or regulations adopted for the purpose of mitigating an environmental effect.	4, 5	NCFEC	None	NCFEC
The alternatives could result in the direct conversion of farmland to non-agricultural uses or conflict with Williamson Act land or agricultural zoning in the Upper Klamath Basin.	1,2, 3, 4, 5	NCFEC	None	NCFEC
Construction activities associated with full or partial Facility removal, the construction of fish passage, or the continued impoundment of water at Copco 2 and J.C. Boyle dams could result in the conversion of forest lands to non-forest use or conflict with forest zoning.	1, 2,3,4,5	NCFEC	None	NCFEC
Continued impoundment of water at the Four Facilities and construction activities associated with the development of fish passage could indirectly convert farmland to non-agricultural use or forest land to non-forest use.	1, 4	NCFEC	None	NCFEC
Ongoing restoration actions could affect land use, agriculture, and forest resources.	1, 4	NCFEC	None	NCFEC
Construction activities associated with Facility removal and the draining of the reservoirs could result in changes in the existing physical environment that could convert farmland to non-agricultural use or convert forest land to non-forest use.	2, 3, 4, 5	LTS	None	LTS
Construction activities associated with dam removal could require new, permanent roads to be constructed to provide access to new recreation areas, which could constitute a change in the existing environment.	2, 3, 5	LTS	None	LTS

Table 4-17. Summary of Land Use, Agricultural and Forest Resources Impacts from Chapter 3

Potential Impact	Alternatives	Significance	Proposed Mitigation	Significance After Mitigation
Construction and restoration activities associated with Facility removal would include the removal and reconstruction of recreation facilities which could affect land use.	2, 3, 5	NCFEC	None	NCFEC
The construction and development of fish passage facilities would require new permanent roads to be created to provide access to the Klamath Hydroelectric Project facilities which could change land use and create conflicts with applicable plans and policies or otherwise cause a significant land use impact due to existing zoning and land uses.	4, 5	LTS	None	LTS
Trap and Haul – Programmatic Measure				
Construction of fish handling facilities for trap and haul operations could change land use.	4, 5	LTS	None	LTS
Keno Transfer				
The transfer of ownership of Keno Facility from PacifiCorp to Reclamation could result in a change in land use.	2,3	NCFEC	None	NCFEC
East and Westside Facilities - Programmatic Measure				
The decommissioning of the East and Westside facilities could impact land use	2, 3	NCFEC	None	NCFEC
Yreka Water Supply Pipeline Relocation – Programmatic Measure				
Dam removal would require the relocation of the Yreka Water Supply Pipeline and could result in a change in Land use	2,3,5	NCFEC	None	NCFEC
Klamath Basin Restoration Agreement - Programmatic Measure				
The KBRA could conflict with applicable land use plans, policies, or regulations adopted for the purpose of avoiding or mitigating an environmental effect.	2,3	LTS	None	LTS
The implementation of the Water Diversion Limitation Program could convert farmland to non-agricultural uses.	2,3	LTS	None	LTS
The Water Use Retirement Program could result in the following or conversion of agricultural land non agricultural uses, such as open space or wetland restoration areas.	2,3	B	None	B
The Power for Water Management Program could affect Land Use in the area of Reclamation's Klamath Project.	2,3	LTS	None	LTS

Table 4-17. Summary of Land Use, Agricultural and Forest Resources Impacts from Chapter 3

Potential Impact	Alternatives	Significance	Proposed Mitigation	Significance After Mitigation
The KBRA's Mazama Forest Project could result in the conversion of forest land to non-forest use or conflict with forest zoning.	2,3	NCFEC	None	NCFEC

Key:

- 1 = No Action/No Project
- 2 = Full Facilities Removal of Four Dams Alternative (Proposed Action)
- 3 = Partial Facilities Removal of Four Dams Alternative
- 4 = Fish Passage at Four Dams Alternative
- 5 = Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative
- NCFEC = No Change From Existing Conditions
- B = Beneficial
- LTS = Less than Significant
- S = Significant
- N/A = Not Applicable

4.4.13.1 Alternative 2: Full Facilities Removal of Four Dams

The Proposed Action result in changes that result in conversion of farmland to non-agricultural use or conversion of forest land to non-forest use. New, permanent roads constructed to provide access to recreation areas could constitute a change in land use. The Proposed Action would require the use of land for temporary access roads, stockpiling, staging, and other general construction activities. These would generally be temporary and would occur on lands designated for industrial (dam) or open space use or on currently inundated lands, and could be returned to their original or alternate use following deconstruction. New, permanent roads associated with achieving public access to the river would be created. However, these roads would be constructed on formerly inundated lands and would not affect land use. There are no other cumulative actions or projects that would result in changes to land use in and around the reservoirs. **There would be no significant cumulative effects associated with land use, agriculture, and forest resources.**

4.4.13.1.1 KBRA - Programmatic Measures

The KBRA could conflict with applicable land use plans, policies, or regulations. The KBRA may conflict with applicable land use plans, policies or regulations because it is designed to enact policies at a regional (basin) level, and may not be consistent with local city or county plans and policies. However, Humboldt County in California and Klamath County in Oregon signed the KBRA, and any subsequent conflicts with their plans and policies would be handled by the county Board of Supervisors/Commissioners or other authorizing body. At this time, no other cumulative actions or projects have been identified that would conflict with applicable land use plans, policies, or regulations adopted for the purpose of avoiding or mitigating an environmental effect. However, additional analysis would be completed when locations and specific KBRA program

details are available. **There would be no significant cumulative effects. Implementation of the KBRA will require future environmental compliance as appropriate.**

Construction of fish handling facilities for trap and haul operations within the Fisheries Reintroduction and Management Plan could change land use. The Fisheries Reintroduction and Management Plan includes trap and haul operations that move fish around Keno Impoundment/Lake Ewuana and Link River during times of poor water quality. Trap and haul operations would require construction of new fish handling facilities near Keno Dam and Link River Dam. At this time, no other cumulative actions or projects have been identified that would conflict with applicable land use plans, policies, or regulations adopted for the purpose of avoiding or mitigating an environmental effect. However, additional analysis would be completed when locations and specific KBRA program details are available. Because these new facilities would likely be built on lands designated for industrial (dam) use, their construction would not likely conflict with applicable plans and policies or otherwise cause a significant land use impact. The potential land use conversions generated by development of trap and haul facilities would not be expected to contribute to any land use effects generated by the hydroelectric facility removal action analyzed above. **There would be no significant cumulative effects. Implementation of the KBRA will require future environmental compliance as appropriate.**

The implementation of the Water Diversion Limitation Program could convert farmland to non-agricultural uses. Implementation of the measures in the WURP could result in conversion of farmland to non-agricultural use in the Off Project areas. The Power for Water Management Program could affect land use in the area of Reclamation's Klamath Project. Several of the KBRA actions and programs have the potential to result in the conversion of agricultural land to non-agricultural uses. This could occur indirectly through the retirement of water rights or as a result of decreases in water diversions, or directly through crop fallowing, short-term water leasing, split season irrigation, natural storage improvement or siting of renewable energy infrastructure on agricultural lands. Overall, the KBRA is intended to provide long-term benefits by ensuring sustainable agriculture. No other cumulative actions or programs have been identified that would convert agricultural lands to non-agricultural uses in the Klamath Basin; however additional analysis would be completed when specific locations and additional KBRA program details are available. **There would be no significant cumulative effects. Implementation of the KBRA will require future environmental compliance as appropriate.**

4.4.13.2 Alternatives 3, 4, and 5

Alternatives, 3, 4, and 5 would have similar cumulative land use impacts as those described for the Proposed Action. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; **therefore there would be no cumulative effects associated with KBRA actions.**

4.4.13.3 Mitigation Measures

No mitigation measures are required, therefore, **no cumulatively considerable adverse effects related to land use and agriculture would occur.**

4.4.14 Socioeconomics

Tables 4-3 and 4-4 identify local, State and Federal plans, programs and projects identified as potential contributors to the cumulative condition. These plans, as well as the decadal population projections described in Table 4-10, provide some information regarding the cumulative context within this project would occur. This section discusses (1) whether the plans, programs or projects identified in Tables 4-3 and 4-4 are sufficiently connected or similar to this project as to magnify or offset the economic impacts of this project, and (2) whether the individual positive and negative socioeconomic effects of this project would result in cumulatively considerable adverse effects.

County economic conditions fluctuate based on local, regional, and national economic conditions. The national economic recession, which started in December 2007, has affected county economies in the area of analysis and employment, income, and output have declined in some sectors. Section 3.15, Socioeconomics, and Appendix O, County Economic Descriptions, detail the existing economic conditions in the area of analysis⁶.

Unemployment rates in 2009 and 2010 have been the highest in the past decade in the eight Klamath Basin counties in the area of analysis, as they have been for most of the counties in California and Oregon. California coastal counties, with the potential to experience marine fishery effects from the proposed alternatives, reflect similar trends. From 1997 to 2008, poverty trends in the eight counties were higher than California and Oregon State averages (U.S. Census Bureau [USCB] 2010a; 2010b).

Total industry earnings⁷ increased from 2005 to 2008 for all counties in the Klamath Basin, but some sectors experienced decreased earnings. In all counties, except Modoc County, which had undisclosed data, earnings in the construction industry decreased from 2005 to 2008 (Bureau of Economic Analysis 2010). The manufacturing sector also had decreased earnings comparing 2005 and 2008 in most counties in the impacted region. This trend is similar to the trends occurring in the larger economy. In Siskiyou County, the quantity of timber harvested declined 2008 and 2009 relative to 2000 through 2007. Data presented in the existing conditions in Section 3.15, Socioeconomics, reflect these cumulative economic effects.

⁶ Data presented in this section and Section 3.15, Socioeconomics, was the most recent data available at the time of the Notice of Preparation. Based on a brief review of 2009 and 2010 data, now available, total industry earnings in the Klamath Basin counties decreased relative to 2008, which is expected based on the national recession.

⁷ Industry earnings are defined as a measure of hourly and weekly earnings of wage and salary workers by occupation and by industry (Bureau of Labor Statistics 2012).

All else equal, the regional economy would likely experience fluctuations in employment and economic output similar to the previous decades. Housing, commercial, transportation, and other development projects under the cumulative condition would help generate activity in the local economy and result in long-term term improvements in overall economic conditions. However, publicly funded projects could face delays as budgets could be constrained at all levels of government. At the local level counties could have smaller operating budgets and tax revenues.

Population growth also helps to generate economic activity. As shown in Table 4-10, population is expected to increase in the area of analysis. As people move into the region, they purchase houses, food, fuel, and other goods and services in the region. As demands for goods and services increase, businesses move into the area and jobs are created. New residents also pay property taxes and sales taxes, typically the largest contributors to county revenues (Table 3.15-19 shows tax revenues for Siskiyou County).

Tables 3.15-65 and 3.15-66 in Section 3.15, Socioeconomics, summarize the regional economic impacts (jobs, labor income, output) of proposed alternatives on each affected sector; these impacts are described quantitatively for Alternatives 2 and 3 and qualitatively for Alternatives 4 and 5. Economic impacts vary in terms of time frame (based on the timing of the impact on a given resource) and affected region (based on where most of the spending associated with a given resource is expected to occur). The magnitude of regional effects is sensitive not only to the magnitude of the direct effect being analyzed but also the size and economic diversity of the affected region. Given the disparate regions used to define economic effects for the affected resources, summing economic effects across resources is not an appropriate way to determine the net economic impact of the alternatives, unless the impacts can be monetized so be readily compared. Simple addition of effects is not possible because the units of measurement are different for impacts on different resources. Absent a method to compare the impacts in a consistent manner using common metrics, it is not possible to compare the relative magnitude of positive and negative effects of each alternative.

Table 3.15-66 includes economic effects of the KBRA, including the Tribal Program on Klamath Basin tribes. Other tribal effects covered in Section 3.15 but not included in Table 3.15-66 are effects of fishery improvements on subsistence, ceremonial and commercial harvests and effects of water quality improvements on tribal cultural practices.

The following sections describe cumulative economic effects of the proposed alternatives. Positive economic effects are presented together as they would improve regional economies under the cumulative conditions. Potential adverse cumulative economic effects are presented separately; however, it is important to recognize that some positive economic effects of the proposed alternatives would be offset by adverse effects of proposed alternatives if they occur in the same economic region.

4.4.14.1 Alternative 2: Full Facilities Removal of Four Dams

Implementation of the Proposed Action under the cumulative condition could affect economic output, employment, and labor income in the short- and long-term. The introduction to this section describes the cumulative condition for regional economies in the area of analysis. The Proposed Action would have some positive effects, summarized in the bullet list below, on the regional economy. Positive economic effects would benefit economies under the cumulative condition and are not further discussed. Adverse effects, which would offset some positive effects, are discussed in more detail below to evaluate the cumulative economic effect. The following summary presents employment effects; regional economic effects pertaining to labor income and output follow the same direction as employment (see Tables 3.15-65 and 3.15-66).

- Short-term impacts pertaining to dam decommissioning would be positive for Klamath and Siskiyou Counties (+1400 jobs).
- Medium-term impacts (about 15 years) would be positive. Mitigation would have positive impacts in Klamath and Siskiyou counties (+220 jobs in total during 2018-2025). KBRA programs would have positive impacts in Klamath, Del Norte, Humboldt and Siskiyou Counties, which would experience total job increases during the 15-year KBRA implementation period as follows: Fisheries Program (+3,917 jobs), Water Resources Program (+243 jobs), Regulatory Assurances (+146 jobs), and Tribal Program (+122 jobs for the Karuk Tribe in Siskiyou County, +120 jobs for The Klamath Tribes in Klamath County, +144 jobs for the Yurok Tribe in Humboldt County). The KBRA County Program designates \$3.2 million for Klamath County and \$20 million for Siskiyou County (numbers of jobs contingent on how the counties would choose to expend these monies).
- Some long-term impacts would be positive: Jobs would increase periodically in Klamath, Siskiyou and Modoc Counties due to irrigated agriculture (+70 to +695 jobs in five modeled drought years, no change in remaining 45 modeled years). Commercial fishing would experience positive impacts, including +218 jobs in San Francisco Bay Area Counties, +69 jobs in Fort Bragg (Mendocino County), +19 jobs in KMZ-CA (Humboldt and Del Norte counties), +11 jobs in KMZ-OR (Curry County), and +136 jobs in Central Oregon (Douglas, Lane and Lincoln Counties). Ocean recreational fishing would experience positive impacts, including +5 jobs in KMZ-CA and +1 job in KMZ-OR. Klamath, Del Norte, Humboldt and Siskiyou Counties would experience positive impacts due to in-river salmon fishing (+3 jobs); steelhead and redband trout impacts would also be positive but are not quantifiable. Impacts in Klamath and Siskiyou Counties would be positive for refuge recreation (+5 jobs).

The regional employment impacts described above include a mix of part-time, full-time and temporary jobs. The estimates are based on modeled results, using 2009 economic data for the counties that encompass each affected region (2009 being the most recent year for which data were available at the time of this analysis). The estimates are more

indicative of the economy's short-term response rather than long-term adjustment to an infusion of money. Regional economies are dynamic and changes in demographics, markets, technology, infrastructure, and other factors may affect how businesses respond over time to such infusions.

In addition to the regional economic impacts summarized above, tribal harvest opportunities would increase under the Proposed Action. Removal of the reservoirs behind the dams would significantly reduce the incidence of late-summer, toxigenic phytoplankton blooms that have prompted postings of public health advisories in the Hydroelectric Reach and further downstream on the Klamath River. These water quality improvements would have beneficial effects on tribal cultural practices that involve water contact.

Long-term job losses in Siskiyou and Klamath Counties as a result of foregone O&M at the Four Facilities would adversely affect the regional economy under the cumulative condition. The introduction to this section describes the cumulative economic condition in the area of analysis, including trends in employment. Reduced employment has had an adverse effect on the regional economy in the cumulative condition. In the long term, counties would implement development projects to meet growth defined in general plans, which would be a positive cumulative effect on the economy. However, the recent economic recession and decreased county budgets may delay some of these projects and associated job opportunities. The Proposed Action would contribute to job losses by eliminating an estimated 49 jobs related to O&M at the Four Facilities. These would be long-term job losses and an adverse cumulative effect. As described above, the Proposed Action would create some jobs in the short- and medium-term that could offset some of these losses.

Decreases in recreational opportunities could affect the regional economy under the cumulative condition. Recreation is an important industry in the area of analysis to support economic activity and growth. In their general plans, counties emphasize the importance of maintaining and creating recreation opportunities in the area. No cumulative projects were identified that would further reduce reservoir/lake based recreation opportunities including reservoir-based fishing, flat water boating, and camping and day use facilities adjacent to a lake. The Proposed Action would permanently remove J.C. Boyle, Copco 1, and Iron Gate Reservoirs, which are frequently visited recreation sites and contribute to economic output, labor income, and jobs. Loss of recreation at the reservoirs would be an adverse cumulative effect to the economies of Siskiyou and Klamath Counties.

Proposed water diversion activities on tributaries (Scott River and Trinity River) to the Klamath River could affect flows and result in a decrease of available flows for recreational activities, namely whitewater boating and fishing. Lower flows could reduce boating opportunities and trips booked in the region, which would be an adverse cumulative economic effect. Loss of whitewater boating opportunities at Hell's Corner Reach under the Proposed Action would also adversely affect Klamath County's economy under the cumulative condition.

Removal of the Four Facilities, in combination with other cumulative projects, could result in increased energy rates for PacifiCorp customers. Under the cumulative condition, PacifiCorp would continue operations to meet customer demands, which may include projects to develop energy sources or changes to customer rates. PacifiCorp sets customer rates based on multiple factors, including energy prices, future demands, resource adequacy, overhead costs, and long-term investments. PacifiCorp's Integrated Resource Plan from 2008 and the 2010 update describes plans included in the cumulative condition to increase the percentage of renewable energy in the company's portfolio, establish new sources of energy to meet the increasing base load and higher peak demands, and upgrade or maintain existing power sources. These actions would affect PacifiCorp's decisions to change customer rates, which in turn are subject to OPUC and CPUC approval. Because of the many factors that PacifiCorp considers in setting customer rates, it is difficult to assess the size of potential rate effects under the cumulative condition. For the Proposed Action, PacifiCorp has added an approximately 2 percent surcharge to customer rates in Oregon and California to cover costs of dam removal, which was approved by the Oregon Public Utilities Commission (OPUC) and California Public Utilities Commission (CPUC). Under the KHSA, ratepayer liability is capped at \$200 million, prorated between PacifiCorp's customers in Oregon (up to \$184 million) and California (up to \$16 million). The Proposed Action has affected customer rates under the Proposed Action; however, customer rates would not likely increase above the existing surcharges as a direct result of dam removal costs.

Removal of the Four Facilities could affect property values of parcels near Copco 1 and Iron Gate Reservoirs. Under the cumulative condition, land values would fluctuate with market conditions. The introduction to this section describes existing economic trends in the area of analysis that could affect property values. The recent economic recession has negatively affected land values. Some planned projects under the cumulative condition, such as those described in city or county planning documents, could increase economic development and lead to an upward trend of property values in the long term under the cumulative condition. In Siskiyou County, median home prices have declined since 2006 (See Real Estate Evaluation Report, Bender Rosenthal, Inc 2011 in Section 3.15, Socioeconomics). Land values have followed similar trends. However, it is speculative to predict how land values would change in the future under the cumulative condition. To the extent that dam removal has not been fully capitalized into property values, reservoir real estate values may continue to decline following a positive Secretarial Determination. This loss in value may be partially offset over the long term as barren landscape becomes revegetated open space. However, some of this loss may be permanent as a shift from reservoir view to no view or from reservoir frontage to river view may make a parcel less desirable. Riverine parcels in areas downstream from Iron Gate Dam that experience detectable improvements in water quality and/or fish availability may experience positive changes in value. Available data are insufficient to quantify such short- and long-term effects of the Proposed Action.

Removal of the Four Facilities could affect tax revenues to Siskiyou and Klamath Counties. The introduction to this section describes existing economic trends in the area of analysis that could affect tax revenues, including property and sales taxes, to local

governments under the cumulative condition. The recession resulted in declines in tax revenues. In the future, economic growth could increase revenues. It is difficult to predict how the economy would fluctuate under the cumulative condition, which generally has a direct effect on local government revenues.

In the short term, if property values decline further and there are no offsetting increases due to other factors, there would be adverse effects to property tax revenues to Siskiyou and Klamath Counties under the cumulative condition. The Proposed Action could contribute to these effects. PacifiCorp owns property around the reservoirs and pays property taxes annually to Siskiyou and Klamath Counties. Annually, PacifiCorp pays in the range of \$290,000 to \$305,000 in property taxes on land attributable to hydroelectric facilities at Copco and Iron Gate Dams and about \$132,000 in property taxes for land attributable to hydroelectric facilities at J.C. Boyle Dam. Under the Proposed Action, the States would assume ownership of these lands and PacifiCorp would not pay property taxes on the relinquished land to the counties. The loss in tax revenue from PacifiCorp owned lands would impact the regional economy. However, if Siskiyou and Klamath Counties receive in-lieu payments of equal value to PacifiCorp property tax payment, there would be no net effect to county revenues under the Proposed Action. Decreased land values and associated property taxes would affect local government revenues. Combined with decreased budgets and revenues as a result of the recession that began in 2007, further reductions in property tax revenues to local governments would be an adverse cumulative effect. In the long term, Siskiyou and Klamath Counties are projecting increased need for housing to support population growth (See Section 4.4.16). Increased homeowners in the counties would increase property taxes to the counties that could offset some losses as a result of the Proposed Action under the cumulative condition in the long term.

The Proposed Action would increase sales tax revenues during the construction period. Construction crews for dam removal in Siskiyou County would purchase goods and services from local restaurants and stores, which would increase sales tax revenues for the counties. Similar to construction worker spending, increased visitation to the counties offering recreation activities would increase sale tax revenues within the counties. Any adverse effects on visitation expenditures would decrease sales tax revenues. Decreases in reservoir recreation in Siskiyou County could reduce sales tax revenues, which would be a and adverse effect. As noted above, under the cumulative condition, income and employment in Klamath and Siskiyou counties has declined between 1997 and 2008. Construction worker spending would be a temporary and positive effect to Siskiyou County under the Proposed Action. The net effect to sales tax revenues from changes in recreation expenditures is unknown. Cumulative effects on county economies would likely vary with some positive and negative effects.

4.4.14.2 Alternative 3: Partial Facilities Removal of Four Dams

Positive cumulative economic effects of Alternative 3 would be similar to the Proposed Action. As indicated in Tables 3.15-65 and 3.15-66, regional employment impacts associated with Alternative 3 would be similar to those for Alternative 2, with the

following exceptions of short-term impacts pertaining to dam decommissioning. Dam decommissioning would be positive but smaller under Alternative 3 (+1100 jobs) than Alternative 2 (+1400 jobs).

The negative impacts under Alternative 3 would be similar to those for Alternative 2 with the exception of O & M. Long-term job losses in Siskiyou and Klamath Counties as a result of foregone O&M at the Four Facilities would adversely affect the regional economy under the cumulative condition. Reduced employment has had an adverse effect on the regional economy in the cumulative condition. In the long term, counties would implement development projects to meet growth defined in general plans, which would be a positive cumulative effect on the economy. Alternative 3 would contribute to job losses by eliminating an estimated 47 jobs related to O&M at the Four Facilities, 2 less than jobs than Alternative 2. These would be long-term job losses and an adverse cumulative effect. Similarly to Alternative 2, Alternative 3 would create some jobs in the short- and medium-term that could offset some of these losses.

The same caveats and uncertainties that apply to Alternative 2 also apply to Alternative 3. As with Alternative 2, short- and medium-term impacts would be positive in all affected regions under Alternative 3. Long-term economic impacts would be positive for coastal counties but more modest and ambiguous for Klamath Basin counties due to the countervailing influence of job losses and gains. Effects on tribal harvests and cultural practices would be positive and similar to effects under Alternative 2.

4.4.14.3 Alternatives 4 and 5

Quantitative estimates of regional economic impacts are not available for Alternative 4 or 5. As indicated in Tables 3.15-65 and 3.15-66, regional impacts of these alternatives can be qualitatively characterized as follows:

- Short-term impacts of construction expenditures associated with fish passage and/or dam removal would be positive under the two alternatives.
- Mitigation would yield some positive medium-term impacts, but the absence of KBRA jobs would mean lower positive impacts relative to Alternatives 2 and 3.
- Long-term positive impacts on irrigated agriculture and refuge recreation attributable to the KBRA under Alternatives 2 and 3 would not occur under Alternatives 4 and 5.
- Commercial, ocean recreational and in-river recreational fisheries would experience positive long-term economic impacts under Alternatives 4 and 5 but to a lesser extent than they would under Alternatives 2 and 3. Positive long-term impacts associated with reservoir and whitewater recreation and operation and maintenance of the dams, which would be foregone under Alternatives 2 and 3, would continue at a diminished level under Alternatives 4 and 5.

In addition to the regional economic impacts cited above, effects of Alternatives 4 and 5 on tribal fish harvest would be positive relative to the No Action/No Project Alternative though of lesser magnitude than Alternatives 2 or 3. However some water quality benefits would occur under Alternative 5 with removal of the two largest dams. Therefore Alternative 5 would lead to some positive effects on tribal cultural practices.

4.4.15 Environmental Justice

Cumulative environmental justice effects would be associated primarily with effects on water quality, aquatic resources, air quality, traffic and noise, and socioeconomics from implementation of the project and other past, present and reasonably foreseeable actions.

The timeframe for environmental justice concerns includes both the duration of construction (May 2019 through December 2020), as some environmental justice issues would only occur during construction (air quality, traffic, noise, water quality, employment), and the years following completion of construction (water quality). The timeframe would extend beyond the construction period indefinitely because impacts on socioeconomics and county revenues would be long term and could continue to occur after construction.

4.4.15.1 Alternative 2: Full Facilities Removal of Four Dams

Dam removal activities could affect fisheries and disproportionately affect tribal people. Dam removal would improve anadromous fisheries in the Klamath River and help recovery of the endangered sucker fisheries. The construction of the Klamath Hydroelectric Facility has resulted in significant cumulative effects on fisheries that have disproportionately affected tribal people because it has blocked access to habitat, impaired water quality, and increased the potential for nuisance algae. The Proposed Action's contribution to this cumulative environmental justice effect would be beneficial. Restored fisheries would help reverse the environmental justice impacts to the tribes that the dams created. Other cumulative actions that would also contribute to restoring fisheries include ongoing restoration actions by the tribes (see Table 4-4), implementation of Klamath Basin TMDLs, the Trinity River Restoration Program, the Five Counties Road Maintenance Program, the Northwest Forest Plan, which contain provisions for improving water quality, restoring habitat, and reduce impacts on fisheries. Together these cumulative actions and the Proposed Action would have environmental justice benefits for tribal people by improving fisheries.

Increased air pollutants and noise associated with dam removal activities could disproportionately affect county residents and tribal people. The traffic on the associated haul roads could disproportionately affect tribal people. Temporary, short term air quality and noise impacts from deconstruction would occur (see Sections 3.9, Air Quality, and 3.23, Noise) that would disproportionately affect Siskiyou and Klamath County residents and tribal people, which as a whole are low income relative to California and Oregon. Implementation of mitigation measures in Sections 3.9, Air Quality, and 3.23, Noise, would reduce the severity of these short term construction impacts. Additionally, residents in Siskiyou and Klamath Counties would be

disproportionately affected by increased traffic on local roads during the construction period. Residents would be subject to short term impacts, such as increased congestion, potential traffic delays, slow moving trucks and potential safety hazards. Section 3.22, Traffic and Transportation identifies measures to be taken to reduce traffic effects of the Proposed Action.

New subdivisions approved for Siskiyou County, timber harvesting, mining, recreation, and agricultural activities could result in significant cumulative air quality, traffic, and noise effects. The Proposed Action's contribution to the cumulative effect would be minimized by implementation of mitigation measures in Sections 3.9, Air Quality, 3.22, Traffic and Transportation, and 3.23, Noise, to reduce the severity of these short-term impacts and would ensure impacts are not disproportionately adverse for tribal people. There would be no long-term cumulative environmental justice effects from construction.

Dam removal activities could provide jobs for county residents and tribal people that are low income and minority. Deconstruction activities would generate jobs in the area of analysis. Approximately 90 construction workers would be hired locally during peak deconstruction period and about 60 workers would be hired locally on average during the deconstruction period from Klamath or Siskiyou Counties. Increased employment would support low income individuals, resulting in a beneficial effect. Any loss in existing recreation or PacifiCorp jobs would be offset by the new jobs created during the decommissioning and deconstruction of the four dams. There are no other cumulative actions such as construction projects that have been identified that would generate a substantial number of local jobs in the area of analysis during the construction period; therefore, there would be no substantial cumulative effects associated with jobs for low income and minority people.

Release of sediment from reservoirs could cause disproportionate short term impacts on county residents and tribal people. The short-term sediment impacts that would occur from reservoir drawdown would be significant for 6-8 months. This could result in a significant cumulative environmental justice effect because of the tribes' dependency on the river for subsistence, cultural ceremonies, and a source of income. The short-term sediment impacts could hurt fisheries or other aquatic plants or animals the tribes rely on. Considering the current decline in fisheries, the high unemployment rates and high poverty rates of the tribes, this could result in cumulative economic and social environmental justice effects. However, the sediment release would be short term in duration. It would occur during the winter to minimize the impacts to fisheries. Because of the short-term nature of the impacts, any potential cumulative effects would be minimal.

Dam removal activities could cause disproportionate long-term water quality impacts on county residents and tribal people. As stated in Sections 3.2, Water Quality, and 3.3, Aquatic Resources, under the Proposed Action water quality would be expected to improve in the Hydroelectric Reach over the long term. Additionally, there would be long-term beneficial effects on dissolved oxygen concentrations and decreased water temperatures downstream from Iron Gate Dam. Ongoing programs and actions in the

Klamath Basin, including implementation of TMDLs to improve water quality, programs identified in Table 4-3 and 4-4 to improve water quality, and actions to improve water quality such as the Five Counties Road Maintenance Program and the Northwest Forest Plan, all have the potential to result in cumulative beneficial effects on water quality.

Therefore, the Proposed Action in addition to other ongoing programs and actions to improve water quality, would contribute to beneficial cumulative environmental justice impacts on water quality.

Changes in county revenues associated with dam removal could decrease county funding of social programs. As described in Section 3.15, Socioeconomics, the Proposed Action could cause a short- and long-term decline in tax revenue to the counties associated with a discontinuation of tax revenue from PacifiCorp and a decrease in property values near the reservoirs. It is speculative to quantify short- and long-term impacts on county social programs because many of these programs receive funding from the State and Federal governments, and would be unaffected by the Proposed Action. However, the recent economic recession and forthcoming budget cuts to Federal, State, and local governments could also result in a decrease in funding of social programs. Together these could create a cumulative effect associated with social program funding. It is not possible to quantify the Proposed Action's contribution to this cumulative effect. The Proposed Action would allow tribal people to gain increased self-reliance and self-sufficiency through increased subsistence and the restoration of the tribal commercial fishery. This might help offset cumulative environmental justice effects associated with social program funding decreases in the long term.

Dam removal activities could disproportionately impact tribal health and social wellbeing in the long term. Ongoing programs and actions in the Klamath Basin, including implementation of programs identified in Table 4-3 and 4-4 to improve fisheries and actions to improve water quality such as implementation of TMDLs, the Five Counties Road Maintenance Program, and the Northwest Forest Plan, all have the potential to result in cumulative beneficial effects on water quality and fisheries. Removal of the dam as part of the KHSA is expected to be beneficial to fall- and spring-run Chinook salmon, coho salmon, and summer and winter steelhead in the long term. Fish population increases would allow the tribes to increase subsistence fishing and once again make fish a larger component of their diet and ceremonies. The Proposed Action, in addition to other ongoing programs and actions to improve water quality and fisheries, would contribute to beneficial cumulative environmental justice impacts on tribal health.

4.4.15.1.1 KBRA - Programmatic Measures

Implementation of the WURP and Interim Flow and Lake Level Program could disproportionately affect low income and minority farm workers. The KBRA proposes voluntary land fallowing and permanent water right sales which could disproportionately affect farm workers in Klamath, Siskiyou, and Modoc Counties. Loss of farm labor jobs could disproportionately affect low-income, minority farm workers, who could lose a portion of their income if farms no longer required their labor. This would be a disproportionate effect on farm workers. Recent drought, regulatory requirements for

fish and stream flows and the resulting water supply unreliability, and the recent economic downturn have contributed to cumulative impacts on agriculture and farm workers in the Klamath Basin. The Proposed Action's contribution to this cumulative impact could be substantial because it could result in loss of jobs and income. However, land fallowing and permanent water rights sales would be voluntary. The impacts on farm workers would depend on the number of willing participants in the Programs. The core of the KBRA is to provide water reliability to farmers, which would ensure continuation of agricultural jobs in the area of analysis. In the long term, the KBRA has the potential to offset any loss of agricultural jobs because of increased water reliability.

Implementation of the Klamath County Economic Development Plan could disproportionately affect low income and minority people in Klamath County. Implementation of the California Water Bond Legislation could disproportionately affect low income and minority people in Siskiyou County. Both Klamath County and Siskiyou County have a larger percentage of persons and families living below the poverty line than their respective States. They also have lower per capita and median family incomes than their respective States. Significant cumulative environmental justice impacts have affected these counties, such as the decline in the timber industry, drought conditions that severely decreased agricultural production, and the recent economic downturn. The KBRA could help to provide some environmental justice benefits to these low income and minority groups in Klamath and Siskiyou Counties. The Klamath County Economic Development Plan would provide \$3.2 million of funding to Klamath County. Funding would support long-term economic growth in Klamath County and could create new job opportunities and improve public programs for county residents. Depending on how funding is used within the county, this action could benefit low income and minority populations. If approved, bond funds would provide \$20 million to Siskiyou County to use for economic development. It cannot be determined at this time how Siskiyou would distribute funds from the California Water Bond Legislation; this is a general discussion. The bond funds could assist Siskiyou County in addressing unemployment, poverty, bankruptcy, and social problems and continuing funding for other county programs. Programs could benefit low income and minority populations in Siskiyou County.

Implementation of the Phase I and Phase II Fisheries Restoration Plans, Tribal Fisheries and Conservation Management Program, Mazama Forest Project, Tribal Programs Economic Revitalization, Fisheries Reintroduction and Management Plan, and Fishery Monitoring Plan could disproportionately affect the tribes. As described in Section 3.16, Environmental Justice, adverse cumulative environmental justice effects on tribes have occurred through the decline in fisheries and the loss of subsistence fishing, including economic, cultural, and social impacts. The KBRA's contribution to this cumulative effect would be beneficial. Implementation of several KBRA programs and projects would have beneficial environmental justice impacts on tribes because they would restore anadromous fish species in the Klamath River and Upper Klamath Basin, return 90,000 acres of the Mazama Forest back to the Klamath Tribes, and provide funding for the Klamath, Karuk, and Yurok Tribes to develop economic revitalization

plans, programs and projects and to assist the tribes in developing their capacity to participate in resource management activities within the basin, particularly relating to tribal fishing and revitalization of tribal subsistence and other economic activities. These actions, and other ongoing river restoration actions, as well as implementation of the KHSA and removal of the Four Facilities, would have cumulative environmental justice benefits on the tribes.

4.4.15.2 Alternatives 3, 4, and 5

Alternatives 3, 4, and 5 would have similar construction-related environmental justice cumulative effects as Alternative 2. Under Alternatives 4 and 5, dams would still block fish passage and increase the potential for disease; therefore, there would be no cumulative benefits on tribes. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; therefore there would be no cumulative effects associated with KBRA actions.

4.4.15.3 Mitigation Measures

No cumulatively considerable adverse effects associated with environmental justice would occur; hence, no mitigation measures are required.

4.4.16 Population and Housing

Cumulative effects on population and housing would be associated with the cumulative need for housing that would result by including the influx of construction workers associated with dam removal and future population growth. The timeframe for population and housing includes the duration of construction (May 2019 through December 2020) because the impacts on population and housing would only occur during construction.

Table 4-18 presents a summary of the potential impacts on population and housing presented in Chapter 3. These impacts are analyzed for cumulative effects below the table.

The 2020 population projection for Siskiyou County is 51,283, an increase of 4,174 from 2010 (Siskiyou County Community Development Department 2010). The Siskiyou County General Plan (2010) states that based on current population and housing trends, there will be a need for an additional 720 new residential units in the county by the year 2014 (Siskiyou County 2010). The projections do not extend to 2020; however, the Lead Agencies assume that there would still be some housing needs within the Siskiyou County.

Klamath County's population is expected to increase from 66,243 in 2008 to 71,440 in 2020 (U.S. Census Bureau, 2006-2008 Community Survey; Klamath County Planning Department 2009). No housing estimates are available for the year 2020. The Klamath Falls urban growth boundary is expected to experience the most growth of all urban areas

Table 4-18. Summary of Population and Housing Impacts from Chapter 3

Potential Impact	Alternatives	Significance	Mitigation	Significance after Mitigation
Construction activities could employ non-local workers, who would need housing for the duration of their employment.	1	NCFEC	None	NCFEC
	2,3,4,5	LTS	None	LTS
Construction, restoration, and monitoring activities associated with new programs could create new jobs and could employ non-local workers, who would need housing for the duration of their employment.	1	LTS	None	LTS
Removal of recreation facilities and related construction activities could result in an increase in construction workers requiring housing.	2,3,5	NCFEC	None	NCFEC
Keno Transfer				
The transfer of ownership of Keno Dam from PacifiCorp to Reclamation could affect population and housing.	2, 3	NCFEC	None	NCFEC
East and Westside Facilities – Programmatic Measure				
The decommissioning of the East and Westside Facilities could impact population and housing.	2, 3	NCFEC	None	NCFEC
Yreka Water Supply Pipeline Relocation – Programmatic Measure				
Dam removal would require relocation of the Yreka Water Supply Pipeline and could result in an increase in construction workers requiring housing.	2,3,5	NCFEC	None	NCFEC
Klamath Basin Restoration Agreement – Programmatic Measures				
Construction and monitoring activities associated with the KBRA programs could employ non-local workers who would need housing for the duration of their employment.	2,3	LTS	None	LTS

- 1 = No Action/No Project
- 2 = Full Facilities Removal of Four Dams Alternative (Proposed Action)
- 3 = Partial Facilities Removal of Four Dams Alternative
- 4 = Fish Passage at Four Dams Alternative
- 5 = Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative
- NCFEC = No Change From Existing Conditions
- B = Beneficial
- LTS = Less than Significant
- S = Significant
- N/A = Not Applicable

in Klamath County over the next 20 years. The forecasted range for the Klamath Falls urban growth boundary population in 2020 is 47,420 to 49,471, from 44,321 in 2007 (Klamath County Planning Department 2009). The Lead Agencies assume there would still be some housing needs in Klamath County.

In 2006, Jackson County's population was 198,615. The Jackson County Comprehensive Plan, Revised Population Element (2007) projects that Jackson County's 2020 population will be 238,865.⁸ The majority of Jackson County's population growth from 1980 to 2005 was in the city of Medford. It is reasonable to assume that Medford will continue to account for a large share of Jackson County's growth in the future (Jackson County 2007). The Comprehensive Plan states that the County has been experiencing a scarcity of workforce housing (low- and middle-income housing), especially from 2002 to 2005 when housing prices rapidly increased. Much of the new housing in Jackson County has been for higher income retirees (Jackson County Undated). Therefore, the Lead Agencies assume there would still be some needs for housing in Jackson County.

4.4.16.1 Alternative 2: Full Facilities Removal of Four Dams

Construction activities could employ non-local workers, who would need housing for the duration of their employment. Implementation of the Proposed Action could create a temporary increase in population as non-local workers migrate to the area for deconstruction. During peak deconstruction periods, implementation of the Proposed Action would require up to 250 total workers with 195 working at the Copco and Iron Gate Facilities combined, and up to 55 workers at the J.C. Boyle Facility. Both of these numbers include administrative and management staff. At the Copco and Iron Gate Facilities, 78 workers would be provided from within the region and 117 would be required from outside of the region. At the J.C. Boyle Facility, 20 workers would come from within the region and 35 from outside of the region. Therefore, the housing need would be up to 117 housing units for the California facilities and 35 housing units for the Oregon facility. Peak worker needs would occur between November 2019 and September 2020.

Population increases are expected for all counties in the area of analysis by the year 2020, and many of the affected counties have noted that housing is needed in the future, especially workforce housing for low- to middle-income groups. The need for housing would be considered a significant cumulative effect. However, the Proposed Action would not have a cumulatively considerable contribution to the cumulative effect. The temporary work force needed for the Proposed Action would likely spread out to cities with available accommodations. It is also possible that some temporary workers would stay in hotels or motels in Klamath Falls or Yreka, local recreational vehicle parks, or available rentals in the rural areas surrounding the dam facilities. The Proposed Action would not require permanent new residences and most workers would leave the area

⁸ The 238,865 projection was made in 2004. A forecast made in 1997 projected the 2020 population to be slightly less at 221,665. The Revised Population Element (Jackson County 2007) presents both projections.

after construction was complete. **The Proposed Action's incremental contribution to the significant cumulative effect associated with population and housing would not be cumulatively considerable.**

4.4.16.1.1 KBRA - Programmatic Measures

Construction and monitoring activities associated with KBRA programs could employ non-local workers who would need housing for the duration of their employment. The creation of jobs and potential need to employ non-local workers could strain local housing availability and result in short and long-term increases in population in communities with the potential to house workers migrating into the area.

Population increases are expected for all counties in the area of analysis by the year 2020, and many of the affected counties have noted that housing is needed in the future, especially workforce housing for low- to middle-income groups. The need for housing would be considered a significant cumulative effect.

The Proposed Action's incremental contribution to this significant cumulative effect would be temporary. It is anticipated that the majority of workers could be satisfied locally. The timing of, and specific locations where, these KBRA programs could be undertaken is not certain, but it is assumed that some of these actions could occur at the same time and in the vicinity of the hydroelectric facility removal actions analyzed above. However, as described in Section 3.17.3, Population and Housing, Existing Conditions/Affected Environment, it is assumed that there is sufficient housing supply in the current stock to temporarily accommodate non-local workers. **The KBRA's incremental contribution to the significant cumulative effect on housing would not be cumulatively considerable. Implementation of the KBRA will require future environmental compliance as appropriate.**

4.4.16.2 Alternatives 3, 4, and 5

Alternatives 3, 4, and 5 would have similar cumulative effects on population and housing as those described for Alternative 2. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; therefore there would be no cumulative effects associated with KBRA actions.

4.4.16.3 Mitigation Measures

There are no cumulatively considerable adverse effects associated with population and housing; therefore, no mitigation measures are required.

4.4.17 Public Health and Safety, Utilities and Public Services, Solid Waste, and Power

Cumulative effects on utilities and public services, solid waste, and public health and safety could occur through increasing the demand for utilities and services, increasing solid waste, and creating additional public health and safety risks. The timeframe for this analysis includes the duration of construction (May 2019 through December 2020).

Cumulative effects on hydropower would be associated with the cumulative demand for power that may exceed generation capabilities. The timeframe for this analysis includes the end of construction (December 2020) and beyond, as the demand for power is expected to be needed indefinitely into the future.

Table 4-19 presents a summary of utilities and public services, solid waste, and public health and safety, and power impacts presented in Chapter 3. These impacts are analyzed for cumulative effects below the table.

Table 4-19. Summary of Public Health and Safety, Utilities and Public Services, Solid Waste, and Power Impacts from Chapter 3

Potential Impact	Alternatives	Significance	Mitigation	Significance after Mitigation
Continued impoundment of water at the reservoirs under annual license renewals would allow hydropower generation to continue subject to the conditions of the Reclamation Biological Opinions, which would have the potential to decrease hydropower production.	1	NCFEC	None	NCFEC
Construction activities related to the ongoing restoration and management activities could impact public health and safety.	1	NCFEC	None	NCFEC
Construction activities from removal of the Four Facilities could result in public health and safety risks.	2, 3, 4, 5	S	PHS-1: Public Safety Management Plan	LTS
Construction activities could increase public hazards by placing construction equipment in waterways, roadways, and other areas accessible by residents, recreational visitors, and potential spectators of the deconstruction activities.	2, 3, 4, 5	S	PHS-1: Public Safety Management Plan; PHS-2: Fire Management Plan	LTS
Construction and demolition activities could increase the risk of wildfires.	2, 3, 4, 5	S	PHS-2: Fire Management Plan	LTS
Removal of the dams would eliminate a water source for wildfire services in the Klamath Basin and could increase response times.	2, 3, 5	LTS	None	LTS
Dam removal would eliminate a water source for residential firefighting in and around Copco Village, and could increase the risk to homes from fire.	2, 3, 5	LTS	None	LTS

Table 4-19. Summary of Public Health and Safety, Utilities and Public Services, Solid Waste, and Power Impacts from Chapter 3

Potential Impact	Alternatives	Significance	Mitigation	Significance after Mitigation
Construction activities could affect police services by temporarily increasing the population of construction workers, lengthening response times due to construction traffic on area roads, and exposing construction areas to theft and/or vandalism.	2, 3, 4, 5	NCFEC	None	NCFEC
Construction activities could require the use of electricity and natural gas supplies in the study area.	2, 3, 4, 5	NCFEC	None	NCFEC
The removal of recreational facilities currently located on the banks of the existing reservoirs could affect public health and safety	2, 3, 5	S	PS-1: Public Safety Management Plan PHS-2: Fire Management Plan	LTS
Construction activities could affect public services and utilities in the counties and cities in the study area.	2, 3, 4, 5	LTS	None	LTS
Construction activities could result in the need for new construction and access roads.	2, 3, 4, 5	LTS	None	LTS
Dam removal would require the construction of new access roads for recreation facilities which could affect public health and safety.	2, 3, 4, 5	LTS	None	LTS
Construction activities (including Signage and Construction Traffic Management BMP) could affect road conditions by increasing traffic from heavy construction vehicles which could affect public health and safety.	2, 3, 4, 5	LTS	None	LTS
Construction activities could generate a substantial amount of solid waste which could affect public services and utilities.	2, 3, 4, 5	LTS	None	LTS
Dam removal would remove existing hydropower facilities, resulting in a loss of hydropower generation which could affect the supply of electricity.	2, 3, 5	LTS	None	LTS
Development of fish passage would reduce power generation at the existing hydropower facilities due to bypass stream flow requirements which could affect the supply of electricity.	4, 5	LTS	None	LTS

Table 4-19. Summary of Public Health and Safety, Utilities and Public Services, Solid Waste, and Power Impacts from Chapter 3

Potential Impact	Alternatives	Significance	Mitigation	Significance after Mitigation
Dam removal could increase available mosquito habitat and could increase the risk of disease transmission in the short term.	2, 3, 5	LTS	None	LTS
Leaving dam facilities and infrastructure in place could have the potential to result in public health and safety risks.	4	NCFEC	None	NCFEC
	3, 5	LTS	None	LTS
Keno Transfer				
The Keno Facility would be transferred to the DOI, which would not cause adverse effects to Public Health and Safety.	2, 3	NCFEC	None	NCFEC
East and Westside Facilities – Programmatic Measure				
The East and Westside Facilities would be decommissioned, resulting in the loss of generated power.	2, 3	LTS	None	LTS
Yreka Water Supply Pipeline Relocation – Programmatic Measure				
Construction activities could affect Yreka's municipal water supply by damaging or exposing the Yreka Water Supply Pipeline prior to its relocation.	2, 3, 5	LTS	None	LTS
Klamath Basin Restoration Agreement – Programmatic Measures				
Prescribed burning and mechanical thinning under the Phase I and II Fisheries Restoration Plans could affect Public Services and Utilities.	2,3	S (short term) B (long term)	PHS-2: Fire Management Plan	LTS/B
Construction activities associated with the KBRA programs could result in public health and safety impacts	2,3	LTS (short term) B (long term)	None	LTS (short term) B (long term)
Implementation of the Power for Water Management Program could create new renewable energy sources.	2,3	B	None	B
Completing the Emergency Response Plan could have beneficial effects on Public Services and Public Safety.	2,3	B	None	B

Key:

The 2020 population projection for Siskiyou County is 51,283, an increase of 4,174 from 2010 (Siskiyou County Community Development Department 2010). The Siskiyou County General Plan (2010) states that based on current population and housing trends, there will be a need for an additional 720 new residential units in the county by the year 2014 (Siskiyou County 2010). Klamath County's population is expected to increase to 71,440 in 2020 (Klamath County Planning Department 2009).

4.4.17.1 Alternative 2: Full Facilities Removal of Four Dams

Construction activities could result in public health and safety risks. Construction activities could increase public hazards by placing construction equipment in waterways, roadways, and other areas accessible by residents, recreational visitors, and potential spectators of the deconstruction activities. Construction activities could increase public hazards by placing construction equipment in waterways, roadways, and other areas accessible by residents, recreational visitors, and potential spectators of the deconstruction activities. Earthwork, blasting, construction vehicles, and work within the waterway could have public safety risks. The placement of construction equipment in areas potentially accessible by residents and recreational visitors would be a safety hazard. Blockage of existing roadways and or use of the roadways for truck hauling of materials would also be a safety hazard. There are no other known actions or projects that would affect public health and safety directly at the reservoir sites during deconstruction. There could be construction of new subdivisions or road improvements adjacent to the reservoirs; however, the timeframe for these projects is not known. If these projects occurred at the same time as dam deconstruction, they could result in significant cumulative public health and safety effects. The Proposed Action's incremental contribution to the cumulative effects would be cumulatively considerable; however, mitigation measures would be implemented to reduce these impacts. A public safety plan (PHS-1) and a Fire Management Plan (PHS-2) would be developed that would ensure measures are taken to protect public safety during deconstruction. With mitigation, **the Proposed Action's incremental contribution to the significant cumulative effect would not be cumulatively considerable.**

Construction and demolition activities could increase the risk of wildfires. The fire threat in the areas surrounding the Four Facilities is categorized as high to very high. Deconstruction activities could further aggravate the risk of fire. Other future actions or projects in the vicinity of the facilities that could also increase the risk of fire include development of new subdivisions, road improvements, and even recreation activities such as camping with fires. A decline in the timber industry and a decrease in timber harvesting has also occurred in Siskiyou County and the surrounding counties. If this trend continues, it could leave more dry flammable brush that could increase the potential for wildfires. Together, these actions could result in significant cumulative risks associated with wildfires. The Proposed Action's incremental contribution to the cumulative effect associated with wildfires would be cumulatively considerable; however mitigation measures would be implemented to reduce these impacts. A Fire Management Plan (PHS-2) would be developed to reduce the risks of fires and ensure fire suppression

tools are on-site at all times. **With mitigation, the Proposed Action’s incremental contribution to the significant cumulative effect would not be cumulatively considerable.**

Removal of the dams could eliminate a water source for wildfire services and could increase response times. Removal of the dams would eliminate a water source for wildfire services and could increase response times. Removal of the reservoirs would reduce accessibility to a water source for residential firefighting, including in and around Copco Village, potentially increasing the risk to homes from fire. Dam removal would reduce accessibility to a source of water for fire services and could therefore increase response times. The Klamath River would remain after dam removal, and surface water modeling (described in Section 3.6, Flood Hydrology, and Section 3.8, Water Supply/Water Rights) indicates that flows in the Klamath River downstream from the removed dams would remain unchanged. As such, helicopter fire crews could still obtain water from the Klamath River, Keno Impoundment/Lake Ewauna, or Upper Klamath Lake. The presence of the Klamath River, existing water systems, and existing fire fighting resources ensures that assets for firefighting are present in the area. No other known actions or projects in the area would substantially change response times or decrease water availability for fire services. **There would be no significant cumulative effects associated with increased response times for fire services or elimination of water sources for firefighting.**

Construction of the Proposed Action could affect the City of Yreka’s municipal water supply. The Proposed Action would require relocating the City of Yreka’s municipal water supply pipeline that is currently under Iron Gate Reservoir. No other known cumulative actions or projects would affect the City of Yreka’s municipal water supply pipeline. **There would be no significant cumulative effects.**

Under the Proposed Action, recreational facilities currently located on the banks of the existing reservoirs would be removed following drawdown and could affect public health and safety. Once the reservoirs are drawn down, existing recreational facilities will be removed. The deconstruction could have health and safety impacts as a result of the construction equipment and work site safety issues. No other known cumulative actions are expected to occur that could affect the public during deconstruction of the recreational facilities. Additionally, Mitigation Measures REC-1 and REC-2 would be implemented to reduce health and safety impacts. **There would be no significant cumulative effects.**

Construction of the Proposed Action could affect public services and utilities in the counties and cities in the area of analysis. The large number of construction workers required for the project could increase the demand on existing services and utilities. Both Siskiyou County and Klamath County are projecting population increases in 2020, and this would also increase the demand for public services and utilities. Together these actions could result in significant cumulative effects associated with the demand for public services and utilities. However, the workers for the Proposed Action would likely stay in existing residences, hotels, or campgrounds with adequate existing utilities and

services. In addition, the workers and their associated utility and service demands would be temporary, and by December 2020 they would likely return to their city or county of origin. No new long-term utility or services demands would occur. **The Proposed Action's incremental contribution to the significant cumulative effect associated with increased demands for utilities and services would not be cumulatively considerable.**

Implementation of the Proposed Action could affect road conditions. Construction equipment could damage existing roads during deconstruction. Siskiyou County has had reduced budgets and has several existing roads that they cannot afford to maintain. Other proposed projects such as the new subdivisions around Iron Gate Dam, mining activities, and general wear and tear from seasonal traffic all contribute to degrade the current road system over time. Together these actions and the Proposed Action would result in significant cumulative effects on road conditions. However, the DRE would be responsible for repairing all damages to roads during deconstruction activities. The use of roads during deconstruction would be temporary and would be over after deconstruction is complete. No long-term use of the roads would occur. **The Proposed Action's incremental contribution to the significant cumulative effect associated with road conditions would not be cumulatively considerable.**

Activities associated with the Proposed Action could generate a substantial amount of solid waste. Deconstruction of the Four Facilities is expected to generate a substantial amount of solid waste. The population in Siskiyou and Klamath Counties is expected to increase in the future. As a consequence of this projected population growth, the generation of solid waste would also be expected to increase proportionally. Solid waste facilities have a finite amount of space and can only accept waste if space is available. The Proposed Action's generation of solid waste, combined with the expected increases in solid waste generation from population increases, and any future construction projects such as the proposed subdivisions described in Table 4-3 above, could create a significant cumulative solid waste impact. The Proposed Action's contribution to the cumulative effect would be less than cumulatively considerable. The earth, concrete, and rebar waste that would be removed from the facilities under the Proposed Action would be sent to local landfills. The selected landfills in the region have adequate capacity to absorb the debris from this temporary project. A portion of the waste would be sent to recycling facilities. The Proposed Action would not create a new permanent stream of solid waste generation; the solid waste impacts would be temporary and only last the duration of construction. **The Proposed Action's incremental contribution to the significant cumulative effects associated with solid waste would not be cumulatively considerable.**

The Proposed Action would remove existing hydropower facilities, resulting in a loss of hydropower. Under the Proposed Action, the East and Westside Facilities would be decommissioned, resulting in the loss of generated power. Under the Proposed Action, four of the seven power generating facilities of the KHP would be removed and the Eastside and Westside Facilities would be decommissioned. The combined output of the

Four Facilities that would be removed is approximately 169 MW, and FERC rates the project's dependable capacity as 42.7 MW⁹ (M-Cubed 2006). The total combined power generating capacity of the Eastside and Westside Facilities is approximately 3.8 MW.

This accounts for less than 2 percent of PacifiCorp's power portfolio. While the loss of the power generated may have some impact to the local area, the effects of the loss to the Northwest Power Pool, in light of the scale of the additional generation needed to meet demand over the next 10 years, is minimal.

Significant cumulative effects have occurred associated with power supply and demand in the west. Declining power supply margins over the next 10 years will require an upgraded transmission system across the western interconnection in order to balance the surplus of generation in the northern and eastern portions with the higher demands in the western and southern areas of the region. Planning for these upgrades has already begun independently of the Proposed Action in order to meet the growing energy demand across the Western States, and construction on several of these projects is already underway. The need for these transmission upgrades was established independently of the Proposed Action and the impacts associated with them cannot be attributed to the potential loss of energy as a result of this project. Many of the major portions of the transmission upgrades will be completed by 2014, prior to the decommissioning of the hydropower facilities discussed in this EIS/EIR.

The need for new generation facilities to meet the needs of PacifiCorp customers has already been established as well. Increasing the percentage of renewable energy in the company's portfolio, establishing new sources of energy to meet the increasing base load demand as well as higher peak demand, and upgrading or maintaining existing power sources are all delineated in PacifiCorp's Integrated Resource Plan from 2008 and the 2010 update. These improvements have been outlined as necessary in order to continue to provide reliable service to their customers, and will occur regardless of the Proposed Action.

One cumulative project has been identified that could potentially supply electricity to the region. The Klamath Falls Bioenergy Facility is in the early stages of planning but has issued a Notice of Intent to file an application from the ODE for construction of a bioenergy facility. This facility would burn wood waste and would produce up to 38.5 MW of electrical power. This might help to offset lost power in the region from removal of the Four Facilities.

⁹ Dependable capacity is the MW output of a generator or group of generators during a period of low water or other operational constraints that coincide with a peak electrical system load -- essentially a worst case generation capacity, where low water coincides with peak demand. The dependable capacity is the number of megawatts that can be produced for at least four to six hours under these conditions. This is generation based on real world operations at a hydropower generating facility, whereas nameplate capacity is the amount of power that the turbines are capable of generating with all other conditions being perfect (CEC 2003).

While the Proposed Action would result in the loss of approximately 173.8 MW of power, it would represent less than 2 percent of PacifiCorp's power portfolio. Independent of the Proposed Action, additional improvements are planned by PacifiCorp to increase power generation to meet growing demands. **The Proposed Action's incremental contribution to the significant cumulative effects associated with the loss of electrical generating capacity/hydropower would not be cumulatively considerable.**

The loss of the reservoirs could increase available mosquito habitat and the increase the risk of disease transmission. No other known actions or projects would affect standing water or increase mosquito habitat. **There would be no significant cumulative effects associated with mosquito habitat and increased risk of disease.**

4.4.17.1.1 KBRA - Programmatic Measures

Implementation of the Power for Water Management Program could create new renewable energy sources. Implementation of the Power for Water Management Program (KBRA Section 17) would provide affordable electricity to allow efficient use, distribution, and management of water. This could also involve the development of renewable energy sources, which would provide green energy. One other project, the Klamath Falls Bioenergy Facility, is in the early stages of planning but has issued a Notice of Intent to file an application from the ODE. This facility would burn wood waste and would produce up to 35 MW of electrical power. Together, these actions could provide new sources of power to the region. **The KBRA's incremental contribution to the cumulative effect on electricity would be beneficial. Implementation of the KBRA will require future environmental compliance as appropriate.**

Completing the Emergency Response Plan could have beneficial effects on Public Services and Public Safety. The Emergency Response Plan is intended to prepare water managers and emergency responders for potential failure of Reclamation's Klamath Project dikes or other facilities that affect the storage and delivery of water to Reclamation's Klamath Project irrigators. The plan would include a process to prepare for potential emergencies, identify available funding sources for responding to emergencies, a prioritization method for funding emergency responses, and a process to implement emergency responses. No other known cumulative actions would involve emergency response for Reclamation's Klamath Project. **There would be no significant cumulative impacts. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

Prescribed burning and mechanical thinning under the Phase I and II Fisheries Restoration Plans could affect Public Services and Utilities. Prescribed burning and mechanical thinning in forests could damage to utility lines from falling trees and branches, and could also require using public resources to monitor and manage burning which can leave other areas more vulnerable during the prescribed burn. There are no other cumulative actions or projects that have been identified that would specifically require the use of public resources such as firefighters or that could damage public

utilities in forests; however the risk of forest fires is high in many areas of the Klamath Basin. If forest fires occurred during prescribed burning, this could put stress on existing public resources such as firefighters. The KBRA's incremental contribution to this cumulative effect would be minimal. All prescribed burns would be scheduled so as to ensure firefighters remain available to assist with any wildfires. **The KBRA's incremental contribution to the cumulative effects on public services would not be cumulatively considerable. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

Construction activities associated with the KBRA programs could result in public health and safety impacts. Potential construction activities could include a variety of restoration actions and habitat improvements. The Fisheries Reintroduction and Management Plan, the Agency Lake/Barnes Ranch project, the Wood River Wetland Restoration Program, and elements of the On-Project Plan contain construction components that could have health and safety issues related to the construction activities.

While the exact locations for some of these actions is not yet known, there could be significant cumulative health and safety impacts if the KBRA actions were to take place adjacent to other large construction projects or in areas with substantial public health and safety risks. The KBRA's incremental contribution to the significant cumulative public health and safety impacts would be minimal. Prior to implementing construction, an applicable public health and safety plan would be developed to ensure construction workers and the public would not be adversely affected during construction and operation. **The KBRA's incremental contribution to the significant cumulative effects associated with public health and safety impacts during construction would not be cumulatively considerable. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

4.4.17.2 Alternatives 3, 4, and 5

Alternatives 3 and 5 would have similar cumulative public health and safety, utility, and services effects as those described for Alternative 2. Alternative 4 would have a smaller workforce and a smaller construction area and would therefore have less cumulative effects on public health and safety, utilities, and services. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; therefore there would be no cumulative effects associated with KBRA actions.

4.4.17.3 Mitigation Measures

There would be no cumulatively considerable adverse effects; therefore, no mitigation measures are required.

4.4.18 Scenic Quality

Cumulative effects on scenic quality could occur through changes in the existing visual character of the area or loss of scenic vistas. The timeframe for this analysis includes the

duration of construction (May 2019 through December 2020) and several months to several years after construction until some vegetation becomes established. Table 4-20 presents a summary of scenic quality impacts identified in Chapter 3. These impacts are then analyzed for cumulative effects below the table.

Table 4-20. Summary of Scenic Quality Impacts from Chapter 3

Potential Impact	Alternatives	Significance	Mitigation	Significance after Mitigation
Continued impoundment of water at the Four Facilities could result in water quality impacts that could have long-term impacts on scenic quality.	1, 4	NCFEC	None	NCFEC
Continued existence of the buildings and other man-made structures could have the impact that they would remain inconsistent with the VRM classification of the surrounding area (where such inconsistency is defined as a criterion of significance).	1, 3, 4, 5	NCFEC	None	NCFEC
Ongoing fish habitat restoration actions could result in short-term and long-term impacts on scenic resources.	1	S (short term from construction); B (long term)	None	S (short term from construction); B (long term)
Dam removal could result in impacts on scenic resources from removal of dams and facilities.	2, 3, 5	B	None	B
The removal of historic properties could result in impacts on scenic resources.	2, 3, 5	S	None	S
Dam removal could result in short and long-term impacts on scenic resources in formerly inundated reservoir areas.	2, 3, 5	S	None	S
Deconstruction and restoration activities could result in short-term impacts on scenic resources in the immediate vicinity of the Four Facilities.	2, 3, 5	S (short term); B (long term)	None	S (short-term); B (long term)
Replacement of the existing wooden Lakeview Bridge just downstream from Iron Gate Dam with a concrete bridge could result in short and long-term impacts on scenic resources.	2, 3	S (short term); LTS (long term)	None	S (short-term); LTS (long term)
Demolition of existing recreation facilities, such as campgrounds and boat ramps, from the reservoir banks to the new river shoreline would result in short and long-term impacts on scenic resources.	2, 3	S (short term); LTS (long term)	None	S (short-term); LTS (long term)

Table 4-20. Summary of Scenic Quality Impacts from Chapter 3

Potential Impact	Alternatives	Significance	Mitigation	Significance after Mitigation
Deconstruction activities could create a new source of light or glare that could adversely affect nighttime views in the area.	2, 3, 4, 5	S	SQ-2: Measures to Reduce Nighttime Light and Glare	LTS
Sediment release during dam and reservoir removal could cause temporary changes in water quality and the appearance of the Klamath River in the area of the dams and downstream from Iron Gate Dam.	2, 3, 5	S (short-term)	None	S (short-term)
Removal of the dams and facilities could result in long-term impacts on scenic resources from changes to water quality.	2, 3, 5	B	None	B
Demolition, construction, and restoration activities for the fishways could cause short-term adverse effects on the scenic vistas in the immediate vicinity of the Four Facilities.	4, 5	S	None	S
Construction of fishways could cause changes in the appearance of the Klamath River in the area of the Four Facilities and downstream from Iron Gate Dam.	4, 5	LTS	None	LTS
Fishways could cause substantial long-term impacts on scenic resources.	4, 5	S	SQ-1: Measures to Minimize Scenery Disturbances	S
Keno Transfer				
Implementation of the Keno Transfer could affect scenic resources.	2, 3	NCFEC	None	NCFEC
East and Westside Facilities – Programmatic Measure				
Decommissioning of the East and Westside canals and hydropower facilities could affect scenic resources.	2, 3	LTS	None	LTS
Yreka Water Supply Pipeline Relocation – Programmatic Measure				
Construction of a new, elevated Yreka Water Supply Pipeline and steel pipeline bridge to support the pipe above the river could result in short and long-term impacts on scenic resources.	2, 3, 5	S	SQ-1: Measures to Minimize Scenery Disturbances	S

Key:

- 1 = No Action/No Project
- 2 = Full Facilities Removal of Four Dams Alternative (Proposed Action)
- 3 = Partial Facilities Removal of Four Dams Alternative
- 4 = Fish Passage at Four Dams Alternative
- 5 = Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative
- NCFEC = No Change From Existing Conditions
- B = Beneficial
- LTS = Less than Significant
- S = Significant
- N/A = Not Applicable
- VRM = Visual Resource Management

4.4.18.1 Alternative 2: Full Facilities Removal of Four Dams

The Proposed Action would result in impacts on scenic resources from removal of the dams and facilities. Removal of all of four dam facilities would result in a change from a reservoir vista to a river vista. No other known cumulative actions or projects would visibly change the scenic character of the Klamath River at the Four Facilities. **There would be no significant cumulative scenic impacts.**

The Proposed Action would result in impacts on scenic resources from the removal of some historic properties. Removal of some properties that are considered historic would occur during dam deconstruction. No other known cumulative actions or projects would remove historic properties along the Klamath River near the Four Facilities. **There would be no significant cumulative scenic impacts associated with removal of historic properties.**

Removal of the Four Facilities could result in short and long-term impacts on scenic resources in formerly inundated reservoir areas. The Proposed Action would remove the dams’ associated reservoirs, and substantial changes would occur in the former reservoir area during drawdown and until restoration is complete. The Klamath River in the vicinity of the reservoirs would be reduced in breadth to its historic channel width and depth, exposing all previously inundated areas except the historic river channel. The receding water would expose reservoir sediments at the bottom of the reservoir. No other known cumulative actions or projects would affect the scenic resources in the previously inundated areas during this time period. **There would be no significant cumulative scenic impacts associated with the exposed reservoir areas.**

Deconstruction and restoration activities could result in short-term impacts on scenic resources in the immediate vicinity of the Four Facilities. Deconstruction activities would have temporary impacts on existing scenic resources around the Four Facilities because of the presence of construction staging and stockpiling. No other known cumulative actions or projects would affect the scenic vistas at the dam sites during deconstruction because this area would be closed to the public. **There would be no significant cumulative scenic vista impacts associated during deconstruction.**

Construction of a new, elevated Yreka Water Supply Pipeline and steel pipeline bridge to support the pipe above the river could result in short and long-term impacts on scenic resources. The new prefabricated steel pipe bridge would likely be three spans with a center span of 200 feet and two end spans of 100 feet. The spans would be supported on concrete piers. The new pipeline would be connected to the existing buried pipeline at each end of the bridge. No other known actions or projects would affect scenic resources in the location of the proposed bridge. **There would be no significant cumulative scenic effects associated with the City of Yreka's elevated water supply pipeline.**

Replacement of the existing wooden Lakeview Bridge just downstream from Iron Gate Dam with a concrete bridge could result in short and long-term impacts on scenic resources. If the Lakeview Bridge is replaced with a concrete bridge in the same location, there would be short-term significant impacts on scenic quality during construction from the presence of construction equipment, and long-term impacts because the wooden bridge would be replaced with a concrete bridge. No other known actions or projects would affect scenic resources in the location of the existing bridge. **There would be no significant cumulative scenic effects associated with the replacement of the Lakeview Bridge.**

Deconstruction of existing recreation facilities and construction of new recreation facilities, such as campgrounds and boat ramps, from the reservoir banks to the new river shoreline would result in short and long-term impacts on scenic resources. The recreation areas located on the edges of the existing reservoirs would be removed once the reservoirs have been drawn down. Removal activities would include deconstruction and site restoration. No other known cumulative actions or projects would affect visual resources in the locations of the recreational facilities to be demolished. **There would be no significant cumulative scenic effects associated with the deconstruction of the recreational facilities along the reservoirs.**

Deconstruction could create a new source of light or glare that could adversely affect nighttime views in the area. Temporary lighting would be erected for nighttime activities, and security lighting might be required during deconstruction. No other known cumulative actions or projects would introduce light or glare at the Four Facilities during deconstruction. **There would be no significant cumulative scenic impacts associated with light or glare.**

Drawdown and removal of the four reservoirs could cause temporary changes in the appearance of the Klamath River in the area of the dams and downstream from Iron Gate

Dam. In the short term, water aesthetics (clarity, turbidity, depth of view, and color) in the receding reservoir and downstream river reaches would likely be affected as the sediment behind the dams erodes and washes downstream. Other projects and actions that could occur during reservoir drawdown and could alter the appearance of the Klamath River could include subdivision developments in Siskiyou County, timber harvesting, mining activities, and large storm events. These could contribute sediment and could change the clarity, turbidity, depth of view, and color of the Klamath River. If one or more of these actions occurred at the same time as reservoir drawdown, there could be significant cumulative effects associated with the visual appearance of the river. The Proposed Action's impacts would be temporary and would occur in the winter when the river may already have a changed appearance from runoff and increased turbidity. Because the Proposed Action's contribution would be temporary and would end after the reservoirs were drawn down, **the Proposed Action's incremental contribution to the significant cumulative effect on the appearance of the Klamath River in the short term would not be cumulatively considerable.**

Removal of the dams and facilities could result in long-term impacts on scenic resources from changes to water quality. As described in Section 3.2, Water Quality, removal of the dams at the Four Facilities is expected to improve water quality in the long term. The changes are expected to reduce the river's summer algae concentrations, resulting in changes in both water clarity and coloration. An improvement in water quality could result in some improvement in scenic resources, such as water clarity or fish viewing opportunities. These improvements would be most noticeable from on-river and riverside viewpoints, and much less noticeable from river canyon roadway and community viewpoints. Other cumulative actions and programs that could also improve water quality on the Klamath River include implementation of TMDLs on the Scott, Salmon, Shasta, and Klamath Rivers as noted in Table 4-3, the Hoopa Valley Tribe Water Quality Control Plan (Hoopa Valley Indian Reservation 2008), the Water Quality Control Plan by the Yurok Tribe (2004) and the Draft Eco-Cultural Resources Management Plan (2010) by the Karuk Tribe that contain measures and programs to improve water quality, various watershed and creek restoration projects by the Hoopa Valley Tribe and Siskiyou County noted in Table 4-4, and the Five Counties Road Maintenance Program. Additionally, the Northwest Forest Plan contains provisions for reducing water quality impacts from timber harvesting and road construction. Together these cumulative actions and programs would contribute to improving water quality in the Klamath Basin and could positively affect scenic resources. **The Proposed Action's incremental contribution to the significant cumulative effect on scenic resources would be beneficial.**

4.4.18.1.1 KBRA - Programmatic Measures

Construction activities associated with the Fisheries Restoration Plan- Phase I and Phase II, Fish Entrainment Reduction, the Klamath Tribes Interim Fishing Site, and the Fisheries Reintroduction and Management Plan could result in impacts on scenic resources or introduce new features into the landscape. Many of the KBRA actions and programs would likely require some type of construction. Construction equipment, vehicles, staging areas, and stockpiling areas could have temporary impacts on scenic resources within localized construction areas. No other cumulative actions or projects

have been identified that would cause significant cumulative effects on scenic resources. However, when specific locations and construction schedules are available, additional analysis would be completed. **There would be no significant cumulative effects on scenic resources. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

The Fisheries Restoration Plan- Phase I and Phase II, Wood River Wetland Restoration Project, Water Diversion Limitations, On-Project Plan, WURP, and Interim Flow and Lake Level Programs could result in long-term impacts on scenic resources. The Fisheries Restoration Plan is intended to benefit fish populations and therefore increase fish viewing opportunities, which would result in beneficial effects to scenic resources. In addition, actions are anticipated to result in scenery more consistent with the naturally established, characteristic landscape. The Wood River Wetland Restoration Project is intended provide additional water storage which could potentially result in scenery more consistent with the naturally established, characteristic landscape. The Water Diversion Limitations, On-Project Plan, WURP, and Interim Flow and Lake Level Programs could result in changes to land uses, including changes from rangeland to water storage areas. These changes have the potential to be beneficial if they result in landscapes (wetlands) that are consistent with the naturally established, characteristic landscape. The only other main cumulative action that would have beneficial effects on scenic resources is the implementation of the KHSA, which would remove reservoirs and restore a portion of the Klamath River to its natural state. Together these actions would have beneficial effects on scenic resources. **The KBRA's incremental contribution to the cumulative effects on scenic resources would be beneficial. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

Construction activities associated with fish collection facilities would introduce new features into the landscape. Trap and haul operations within the Fisheries Reintroduction and Management Plan would require construction of fish collection and handling facilities below Keno and near Link River Dams to seasonally move fish around Keno Impoundment/Lake Ewauna and Link River during times of poor water quality. Constructing these facilities would result in temporary impacts on scenic resources at Keno and Link River Dams, and the fish handling facilities would remain in the long term to change the visual landscape. The handling facilities would not be in the same visual area as the Four Facilities; therefore, construction of fish handling facilities would not compound the effects of facility removal actions. No other cumulative actions or projects have been identified that would affect scenic resources at Keno and Link River Dams. **There would be no significant cumulative effects associated with fish collection facilities. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

Fish Entrainment Reduction could result in long-term impacts on scenic resources. Construction activities associated with fish collection facilities below Keno Dam and above Klamath Lake would introduce new features into the landscape. Construction

activities associated with fish collection facilities below Keno Dam and above Klamath Lake would introduce new features into the landscape. The impact to scenic resources from the addition of the fish management and entrainment reduction structures would likely be inconsistent with the naturally established, characteristic landscape. No other cumulative actions or projects would introduce structures into the waterway at these locations. **There would be no significant cumulative effects on scenic resources. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

4.4.18.2 Alternatives 3, 4, and 5

Alternatives 3 and 5 would have similar cumulative scenic effects as those described above for Alternative 2. Alternative 4 would not have any cumulative scenic effects associated with reservoir drawdown or reservoir removal. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; therefore there would be no cumulative effects associated with KBRA actions.

4.4.18.3 Mitigation Measures

There would be no cumulatively considerable adverse effects; therefore, no mitigation is required.

4.4.19 Recreation

Cumulative effects on recreation would be associated with changes in the available recreational facilities and/or opportunities adjacent to the Klamath River, reservoirs, and within the Klamath Basin. The timeframe for recreation therefore includes the duration of construction (May 2019 through December 2020) and continues indefinitely afterwards because post-construction impacts would be permanent. No cumulative projects were identified that would further reduce reservoir/lake based recreation opportunities including reservoir-based fishing, flat water boating, and camping and day use facilities adjacent to a reservoir. This analysis does not include effects discussed as part of the Wild and Scenic Rivers analysis in Chapter 3. Table 4-21 presents a summary of the recreation impacts described in Chapter 3. These impacts are analyzed for cumulative effects below the table.

There are no known past, present, or future actions or projects that would substantially alter recreation facilities or recreation opportunities along the Klamath River. There are, however, a number of ongoing actions to improve fisheries, including the Trinity River Restoration Program, the Five Counties Road Management Program, and the Klamath Basin Conservation Area Restoration Program. These would benefit recreational fishing.

Table 4-21. Summary of Recreation Impacts from Chapter 3

Potential Impact	Alternatives	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Continued existence of the reservoirs could change existing recreation access and opportunities.	1,4	NCFEC	None	NCFEC
Construction activities associated with ongoing programs could temporarily restrict access to recreational opportunities.	1	LTS	None	LTS
Construction activities associated with ongoing programs could result in short-term water quality impacts which could affect recreational opportunities.	1	LTS	None	LTS
Ongoing actions correcting fish passage issues, reintroducing and monitoring fish species, and restoring aquatic habitat could increase recreational fishing and wildlife viewing opportunities in the basin.	1	B	None	B

Key:

- 1 = No Action/No Project
- 2 = Full Facilities Removal of Four Dams Alternative (Proposed Action)
- 3 = Partial Facilities Removal of Four Dams Alternative
- 4 = Fish Passage at Four Dams Alternative
- 5 = Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative
- NCFEC = No Change From Existing Conditions
- B = Beneficial
- LTS = Less than Significant
- S = Significant
- N/A = Not Applicable

There are no known past, present, or future actions or projects that would substantially alter recreation facilities or recreation opportunities along the Klamath River. There are, however, a number of ongoing actions to improve fisheries, including the Trinity River Restoration Program, the Five Counties Road Management Program, and the Klamath Basin Conservation Area Restoration Program. These would benefit recreational fishing.

4.4.19.1 Alternative 2: Full Facilities Removal of Four Dams

Demolition activities could temporarily restrict recreational access in the vicinity of the reservoirs. Short-term demolition activities associated with dam removal would result in temporary loss of access to recreational facilities at the Four Facilities and associated reservoir-based recreational opportunities. No other known actions or projects from May 2019 through December 2020 would occur that would restrict recreation access along the Klamath River. **There would be no significant cumulative impacts associated with restricted recreation access during deconstruction.**

Temporary impacts from demolition activity (i.e., increased noise and dust) could decrease the quality of recreational experiences in the vicinity of the reservoirs. No other known actions or projects from May 2019 through December 2020 would occur that would restrict recreation access along the Klamath River. **There would be no significant cumulative impacts associated with a decrease in the quality of recreational experiences due to demolition activities.**

Facility removal would permanently decrease the availability of reservoir/lake-based recreational opportunities in the area of analysis. The removal of the Facilities would eliminate existing opportunities for reservoir-based recreation activities, such as power boating, waterskiing, lake swimming, and flat-water boat and shore angling, provided at J.C. Boyle, Copco 2, and Iron Gate Reservoirs. No other cumulative projects were identified that would further reduce reservoir/lake based recreation opportunities including reservoir-based fishing, flat-water boating, and camping and day use facilities adjacent to a lake in the Klamath Basin. **There would be no significant cumulative effects associated with the decrease of reservoir/lake based recreation.**

Facility removal could permanently remove recreational facilities associated with the reservoirs. Under the Proposed Action, the recreational facilities constructed to accommodate reservoir recreation, with the exception of Topsy Campground, Fall Creek and Jenny Creek Day Use Areas, and the Iron Gate Fish Hatchery Day Use Area, would be completely removed and the former recreation areas, parking areas, and access trails would be regraded and revegetated (O'Meira et al. 2010). No actions or projects were identified that would further reduce recreation opportunities along the Klamath River. **There would be no significant cumulative effects associated with the removal of the reservoir recreation facilities.**

Facility removal could adversely affect developed recreational facilities upstream and downstream from the subject reservoirs. No actions or projects were identified that would substantially change recreation facilities upstream or downstream from the reservoirs. **There would be no significant cumulative effects associated with recreation facilities upstream or downstream from the Four Facilities.**

Sediment release downstream during reservoir drawdown could decrease the quality of water-contact-based recreational opportunities. The increase in turbidity would reduce visibility and water clarity and this could affect recreation. Other actions that could occur in the Klamath Basin that could increase turbidity include construction of new subdivisions around Iron Gate Dam in Siskiyou County listed in Table 4-4, mining activities, timber harvesting, agricultural activities, road improvements, and large storm events. Together, these could result in high levels of turbidity that could cause significant cumulative water quality effects that could decrease the quality of water-based recreation. The Proposed Action's contribution to this effect would be minimal. The Proposed Action's effects on turbidity would be temporary and almost all the sediment would likely be flushed to the ocean in about two years or less. The Proposed Action would only affect turbidity levels downstream from Iron Gate Dam.

The Proposed Action’s incremental contribution to the significant cumulative effect on the quality of water-contact based recreational opportunities in the short term would not be cumulatively considerable.

Changes in water quality associated with dam removal could positively affect water-contact-based recreational opportunities. Facility removal is expected to result in long-term improvements in water quality that could benefit water-contact-based recreational activities. Many other past, present, and future cumulative actions and programs are taking place or are planned to take place in the Klamath Basin to improve water quality, including the implementation of TMDLs on the Scott, Salmon, Shasta, and Klamath Rivers as noted in Table 4-3, the Hoopa Valley Tribe Water Quality Control Plan (Hoopa Valley Indian Reservation 2008), the Water Quality Control Plan by the Yurok Tribe (2004) and the Draft Eco-Cultural Resources Management Plan (2010) by the Karuk Tribe that contain measures and programs to improve water quality, various watershed and creek restoration projects by the Hoopa Valley Tribe and Siskiyou County noted in Table 4-4, and the Five Counties Road Maintenance Program. Additionally, the Northwest Forest Plan contains provisions for reducing water quality impacts from timber harvesting and road construction. Together these cumulative actions and programs would contribute to improving water quality in the Klamath Basin and could positively affect water-contacted based recreation. **The Proposed Action’s incremental contribution to the cumulative effects on the quality of water-contact-based recreational opportunities in the long term would be beneficial.**

Facility removal could impede access for whitewater boating opportunities. In the reaches between the existing dams, particularly in the Hell’s Corner reach, whitewater boating access would likely be affected due to dam removal activities and sedimentation. No cumulative actions or projects have been identified that would further reduce whitewater boating opportunities along the Klamath River during deconstruction. **There would be no significant cumulative effects associated with access for whitewater boating.**

Facility removal could increase the number of days with acceptable flows for various whitewater boating and recreational fishing in the Keno Reach and reaches downstream from Iron Gate Dam. Dam removal could increase the number of days with acceptable flows for whitewater boating and recreational fishing in the J.C. Boyle and Copco 2 Bypass Reaches.. Dam removal could decrease the number of days with acceptable flows for whitewater boating in the Hell’s Corner Reach. No other known actions or projects would change the number of days with acceptable flows for water-based recreation on the Klamath River. **There would be no significant cumulative effects associated with reducing the number of days with acceptable flows for recreation activities.**

Facility removal would result in increased fisheries populations and abundance, which would improve recreational fishing along the river. Removal of the Facilities would improve habitat conditions for anadromous fish species and is expected to result in increased populations of these species. The increased fisheries populations and abundance would increase the opportunity for recreational fishing. Many other ongoing programs are intended to improve fisheries in the Klamath River and its tributaries,

including the Trinity River Restoration Program, the Five Counties Road Management Program, and the Klamath Basin Conservation Area Restoration Program. Together, these actions and the Proposed Action could result in cumulatively beneficial effects on recreational fishing. **The Proposed Action's incremental contribution to the significant cumulative effect on recreational fishing would be beneficial.**

4.4.19.1.1 KBRA - Programmatic Measures

Construction activities associated with the Phase I Fisheries Restoration Plan could temporarily restrict recreational access. Although specific plans have not yet been developed, floodplain rehabilitation would likely involve the use of heavy equipment along floodplain and riparian areas and therefore could result in restrictions to public access for recreational activities. No other cumulative actions or projects have been identified that could potentially restrict recreation access on the Klamath River. **There would be no significant cumulative effects associated with restricted recreation access. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

Construction activities associated with KBRA programs could result in short-term water quality impacts that could affect recreational opportunities. Erosion and sedimentation during construction activities has the potential to temporarily decrease water quality and reduce water visibility for boaters, swimmers, and fisherman. These short-term water quality impacts would be anticipated to occur throughout the basin where construction activities take place. Specific sections of the river could be affected for a period of time throughout implementation of the KBRA programs. BMPs would be implemented to reduce erosion and sedimentation during construction. Following implementation and related construction activities for KBRA programs including the Interim Flow and Lake Level Program, WURP, water quality and clarity would be expected to improve.

Other actions that could occur in the Klamath Basin that could increase turbidity include reservoir drawdown associated with the KHSAs, construction of new subdivisions noted in Table 4-4, mining, timber harvesting, road improvements, recreation, and agricultural activities. Together, these could result in high levels of turbidity that could cause significant cumulative water quality effects that could decrease the quality of water-based recreation. The KBRA's contribution to this effect would be minimal. The KBRA's effects on turbidity would be temporary and would be controlled with best management practices. **The KBRA's incremental contribution to the significant cumulative effect on water quality that could decrease the quality of water-contact based recreational opportunities would not be cumulatively considerable. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

Fire treatment proposed in the Fisheries Restoration Plan could alter the visual setting and result in decreased recreational visitors to the Klamath Basin. Implementation of the Fisheries Restoration Plan would likely include some sort of fire treatment throughout the basin. It is expected that large or severe burn treatments would result in a short-term adverse effect of the visual quality of the burned area, which could directly affect the

number of recreational visitors to the area (i.e., depending on the size and intensity of the burn, recreationalists may be less likely to visit an area immediately after a prescribed burn than an unburned area). However, long-term visual quality benefits typically result from burn treatments that are consistent with the historic range of the ecosystem. No other cumulative actions are projects have been identified that would substantially alter the visual setting of the basin through proscribed burning that could decrease recreational visitors to the basin. **There would be no significant cumulative impacts associated with altering the visual setting and decreasing recreational visitors to the Klamath Basin. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

KBRA actions correcting fish passage issues, reintroducing and monitoring fish species, and restoring aquatic habitat could increase recreational fishing and wildlife viewing opportunities in the basin. It is expected that correction of fish passage issues throughout the basin would restore fish access to new and historic habitats and result in increased fish populations. The increased fish populations and abundance would beneficially affect recreational fishing opportunities. More specifically, the increased abundance would allow for increased catch limits and fewer catch and release requirements, as well as decrease the potential of closures of entire fishing seasons as those that occurred on the Klamath River in the recent past. Many other ongoing actions or programs are intended to improve fisheries in the Klamath River and its tributaries, including the removal of the Four Facilities as part of the KHSA, the Trinity River Restoration Program, the Five Counties Road Management Program, and the Klamath Basin Conservation Area Restoration Program. The Northwest Forest Plan contains provisions to reduce impacts from timber harvesting on aquatic species and habitat. Other stream and watershed restoration actions, such as those being completed by the Hoopa Valley Tribe and Siskiyou County (see Table 4-4) would also improve fisheries. Together, these actions and the Proposed Action could result in cumulatively beneficial effects on recreational fishing. **The Proposed Action's incremental contribution to the significant cumulative effect on recreational fishing would be beneficial. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

KBRA programs resulting in long-term water quality improvements could increase recreational opportunities throughout the Klamath Basin. KBRA programs including the Fisheries Restoration Plans Phase I and II, Fisheries Reintroduction and Management Plan Phase I and II, WURP, and Interim Flow and Lake Level Program would result in long-term benefits to water quality throughout the Klamath Basin. No other cumulative actions or projects have been identified that would increase recreational opportunities in the Klamath Basin. **There would be no significant cumulative effects associated with increased recreational opportunities in the Klamath Basin. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

KBRA programs that enhance terrestrial wildlife and plant resources could increase recreational opportunities throughout the Klamath Basin. KBRA programs would result

in long-term benefits to terrestrial species as a result of restored floodplain and riparian vegetation and habitat areas. It is anticipated that improvements and increases in terrestrial wildlife habitat would benefit recreational wildlife viewing and recreational hunting opportunities in the Klamath Basin. Other cumulative actions and programs identified in the Klamath Basin that would also contribute to enhancing wildlife and plant resources include California Wildlife: Conservation Challenges (California Department of Fish and Game [CDFG] 2005), which is California's Wildlife Action Plan and outlines measures for conservation of wildlife and habitat, the Riparian Bird Conservation Plan (Riparian Habitat Joint Venture 2004), which provides conservation guidance and implements various programs for riparian bird species in California, and the California Essential Habitat Connectivity Project: A Strategy for Conserving a Connected California (CDFG and Caltrans 2004), which provides information on wildlife corridors that will be used to help implement the Wildlife Action Plan, and will encourage consideration of wildlife corridors for transportation and land use planning projects. Together, these would have beneficial cumulative impacts on terrestrial vegetation and wildlife. **The KBRA's incremental contribution to the cumulative effects on terrestrial and wildlife species that could increase recreational opportunities throughout the Klamath Basin would be beneficial. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

4.4.19.2 Alternatives 3, 4, and 5

Alternative 3 would have similar cumulative recreation effects as Alternative 2. Alternative 4 would not have any cumulative recreation effects, beyond potentially improving fish passage and therefore improving recreational fishing. Alternative 5 would have similar cumulative effects as Alternative 2 but because two dams would remain in place, cumulative benefits to water quality and fisheries would be less. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; therefore there would be no cumulative effects associated with KBRA actions.

4.4.19.3 Mitigation Measures

There are no cumulatively considerable recreation effects; therefore, no mitigation measures are required.

4.4.20 Toxic/Hazardous Materials

Cumulative toxic and hazardous materials effects could occur from future projects in the vicinity of the Four Facilities that could require the use, transport, or disposal of hazardous materials, or that could involve the accidental release of hazardous materials around the Four Facilities. The timeframe for cumulative effects associated with toxic and hazardous materials includes the duration of construction (May 2019 through December 2020). No permanent toxic or hazardous materials would occur after construction is complete. Table 4-22 presents a summary of the toxic and hazardous materials impacts presented in Chapter 3. These impacts are analyzed for cumulative effects below the table.

Table 4-22. Summary of Toxic/Hazardous Materials Impacts from Chapter 3

Potential Impact	Alternatives	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Continued operation of the Four Facilities could create a hazard to the public or the environment through the transport, use, or disposal of hazardous materials.	1, 4, 5	NCFEC	None	NCFEC
Construction activities could create a hazard to the public or the environment if they are located on a site which is included on a list of hazardous materials sites.	2, 3, 4, 5	NCFEC	None	NCFEC

Construction activities associated with the KBRA programs could create a hazard to the public or the environment through the accidental release of hazardous materials during construction activities.	2,3	LTS	None	LTS

Key:

- 1 = No Action/No Project
- 2 = Full Facilities Removal of Four Dams Alternative (Proposed Action)
- 3 = Partial Facilities Removal of Four Dams Alternative
- 4 = Fish Passage at Four Dams Alternative
- 5 = Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative
- NCFEC = No Change From Existing Conditions
- B = Beneficial
- LTS = Less than Significant
- S = Significant
- N/A = Not Applicable

There are no known actions or projects that would occur directly at the Four Facilities that could contribute to cumulative hazardous or toxic materials impacts. There are several new subdivisions proposed around Iron Gate Dam and several road improvements proposed for Siskiyou County. If these actions occur at the same time as dam removal, they could contribute to cumulative hazardous and toxic materials impacts through the use, storage, disposal, and accidental release of hazardous materials.

4.4.20.1 Alternative 2: Full Facilities Removal of Four Dams (Proposed Action)

Facility deconstruction could create a hazard to the public or the environment through the transport, use, or disposal of hazardous materials during construction. Facility deconstruction could create a hazard to the public or the environment through the abatement and disposal of asbestos and lead-based paint during construction.

Drawdown of the reservoirs would require removal of recreational facilities currently located on the banks of the existing reservoirs. The decommissioning of the East and Westside Facilities could have adverse effects in terms of toxics and hazards. The Proposed Action would involve the use, transport, and disposal of hazardous materials during deconstruction. In addition, deconstruction activities may uncover hazardous materials. Future development such as the proposed subdivisions near Iron Gate Dam or road improvements, mining, or agricultural activities could also involve the use,

transport, or disposal of hazardous materials in and around the dam sites. Together these projects and the Proposed Action could result in significant cumulative effects on the public or the environment if they occurred simultaneously. The Proposed Action's incremental contribution to the cumulative effect would not be cumulatively considerable. The Proposed Action's contribution to any toxic and hazardous materials cumulative effects would be minimized by a hazardous materials management plan that would contain measures for proper handling and transport to prevent hazardous materials effects on the public and environment. No schools exist within 3 miles of the project site; therefore, no schools would be exposed to hazardous materials. **The Proposed Action's incremental contribution to significant cumulative effects associated with toxic and hazardous materials would not be cumulatively considerable.**

Facility deconstruction could create a significant hazard to the public or the environment through the accidental release of hazardous materials into the environment during construction. Removal of Iron Gate Reservoir would require the relocation of the Yreka Water Supply Pipeline, which could create a significant hazard to the public or the environment through the accidental release of hazardous materials into the environment during construction. Some equipment and deconstruction activities may require the use and storage of hazardous materials on-site. An accidental release of these materials could pose a threat to the public and the environment. Future development such as the proposed subdivisions near Iron Gate Dam or road improvements could also accidentally uncover or release hazardous materials in and around the dam sites. Together these projects and the Proposed Action could result in significant cumulative effects on the public or the environment. The Proposed Action's incremental contribution to the cumulative effect would not be cumulatively considerable. The Proposed Action's contribution to any toxic and hazardous materials cumulative effects would be minimized by a health and safety plan and a hazardous materials management plan that would contain measures for proper handling, storage, and transport of hazardous materials, as well as spill prevention measures to be implemented on-site. Proper clean up equipment would be required to be kept on-site in the case of accidental spills or releases. **The Proposed Action's incremental contribution to the significant cumulative effects associated with the accidental release of toxic and hazardous materials would not be cumulatively considerable.**

4.4.20.1.1 KBRA - Programmatic Measures

Construction activities associated with the Fisheries Restoration Plan- Phase I and Phase II and Fish Entrainment Reduction could create a significant hazard to the public or the environment through the transport, use, or disposal of hazardous materials encountered or through the accidental release of hazardous materials during construction. The KBRA could require the transport, use, and disposal of hazardous materials and has the potential to result in accidental releases of such materials during construction. While the specific locations and schedules for KBRA actions are currently unknown, the KBRA actions could combine with other actions requiring the transport, use, or disposal of hazardous materials, such as road construction, mining, or agricultural activities, and could result in significant cumulative hazardous impacts. The KBRA's contribution to the significant cumulative effect would be minimal. A health and safety

plan and a hazardous materials management plan that would contain measures for proper handling, storage, and transport of hazardous materials, as well as spill prevention measures to be implemented on-site. Proper clean up equipment would be required to be kept on-site in the case of accidental spills or releases. **The KBRA's incremental contribution to the cumulative effect on hazardous materials would not be cumulatively considerable. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

4.4.20.2 Alternatives 3, 4, and 5

Alternatives 3, 4 and 5 would have similar cumulative hazardous effects as those described for Alternative 2; however, Alternative 4 would not require the removal of any dams and would therefore not contribute to cumulative effects associated with handling and disposal of hazardous materials from hydroelectric facilities and infrastructure. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; therefore there would be no cumulative effects associated with KBRA actions.

4.4.20.3 Mitigation Measures

There would be no cumulatively considerable effects; therefore, no mitigation measures are required.

4.4.21 Traffic and Transportation

Cumulative effects on transportation would be associated with the cumulative ambient background growth in traffic volumes that would result from traffic associated with the dam removal and future actions or projects that may temporarily or permanently increase traffic levels in the area of analysis. The traffic analysis presented in Section 3.22, Traffic and Transportation, in Chapter 3 already considers the dam removal traffic impacts and those of background growth in traffic volumes for the years of construction. For the transportation analysis in Chapter 3, ambient background growth was calculated and superimposed on baseline traffic volumes before applying additional "project related" traffic volumes to the roadways for analysis. This method ensures the accounting of traffic growth out to the planning timeframe.

Therefore, this cumulative analysis focuses on future projects or actions that could occur that might increase traffic levels in the area. This analysis is performed on a qualitative level rather than a quantitative level because the future timeframe for implementation of the Proposed Action and alternatives makes it difficult to accurately predict all actions or projects that could be implemented and contribute cumulative traffic impacts. The timeframe for this cumulative effects analysis includes the duration of construction as no permanent traffic impacts would occur from the Proposed Action or alternatives. Table 4-23 presents a summary of the traffic and transportation impacts described in Chapter 3. These impacts are then analyzed for cumulative effects below the table.

Table 4-23. Summary of Traffic and Transportation Impacts from Chapter 3

Potential Impact	Alternatives	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Traffic Flow Effects				
Construction vehicle trips could result in temporary traffic flow effects on I-5, OR66, US97, and access roads.	2, 3, 4, 5	LTS	None	LTS
	1	S	Traffic Management BMPs	LTS
Construction vehicle trips could result in temporary traffic flow effects on on-site roads.	2, 3, 4, 5	LTS	None	LTS
	1	NCFEC	None	NCFEC
Construction vehicle trips during removal of recreation facilities associated with dam removal could result in temporary traffic flow effects on I-5, OR66, US97, and access roads.	2, 3, 5	LTS	None	LTS
Implementation of the interim measures (IM's) 8 J.C. Boyle Bypass Barrier Removal and IM 16 Water Diversions could result in temporary traffic flow effects on I-5, OR66, US97, and access roads.	1 (IM 8); 2 (IM 8 and 16)	LTS	None	LTS
Traffic Safety Effects				
Construction vehicle trips could cause traffic safety effects associated with the creation of dust along gravel roads.	2, 3, 5	LTS	None	LTS
Construction vehicle trips could cause traffic safety effects associated with vehicle turnouts along Copco Road, Topsy Grade/Ager-Beswick Road and OR66.	2, 3, 4, 5	LTS	None	LTS
Construction vehicle trips could cause traffic safety effects associated with sharp curves along Copco Road and OR66.	2, 3, 5	LTS	None	LTS
The removal of existing recreation facilities from the banks of the existing reservoirs and replacement with new recreations facilities down slope to the new river bed could result in traffic impacts along adjacent roadways.	2	LTS	None	LTS

Table 4-23. Summary of Traffic and Transportation Impacts from Chapter 3

Potential Impact	Alternatives	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Changes in traffic safety could occur.	1	NCFEC	None	NCFEC
Implementation of IM 7 J.C. Boyle Gravel Placement could cause traffic safety effects associated with sharp turns along Copco Road and OR66.	1,2,3	LTS	None	LTS
Implementation of IM's 8 J.C. Boyle Bypass Barrier Removal could cause traffic safety effects associated with sharp turns along Copco Road and OR66.	1,2,3	LTS	None	LTS

- LTS = Less than Significant
- S = Significant
- N/A = Not Applicable

Actions or projects that could contribute to cumulative traffic impacts include construction of new subdivisions in Siskiyou County, and road improvement projects planned by Siskiyou County Public Works, Klamath County, and Jackson County, as noted in Table 4-3 above. Ongoing mining, timber harvesting, recreation, and agricultural activities could also contribute to cumulative traffic impacts and are considered.

4.4.21.1 Alternative 2: Full Facilities Removal of Four Dams

4.4.21.1.1 Traffic Flow Effects

Deconstruction activities associated with the Proposed Action would result in temporary traffic flow effects on Interstate-5 (I-5), OR66, US97, and access roads. Deconstruction activities would increase traffic on I-5, OR66, US97, and access roads to the Four Facilities. Several projects or actions in the area of analysis that would also likely increase traffic include various approved subdivisions in Siskiyou County noted in Table 4-4 and mining operations in Siskiyou County. Road improvement projects planned by Siskiyou County Public Works, Klamath County, and Jackson County could also affect traffic on access roads or highways by increasing the number of construction vehicles or diverting traffic onto other roads. However, current traffic does not exceed the existing Level of Service (LOS) or volume to capacity (v/c) ratios and future traffic with planned growth is not expected to exceed these. The Proposed Action’s contribution to this cumulative effect would be minimal. None of the main roads in the area of analysis would experience volumes in excess of their planned LOS or volume to capacity (v/c) ratio due to traffic resulting from implementation of the Proposed Action. Additionally, the traffic impacts would only occur for the duration of deconstruction. No

permanent traffic effects would occur. **There would be no significant cumulative traffic flow effects on I-5, OR66, US97, or access roads.**

Deconstruction activities associated with the Proposed Action would result in temporary traffic flow effects on on-site roads. Construction activities associated with the demolition of recreation facilities would result in temporary traffic flow effects on I-5, OR66, US97, and access roads. Construction activities related to the relocation of the Yreka Water Supply Pipeline would result in temporary traffic flow effects on I-5, OR66, US97, and access roads. The Proposed Action would require the removal of existing recreation facilities from the banks of the reservoirs and construction of new recreation facilities down slope to the new river bed. The short but frequent heavy vehicle trips anticipated as part of dam deconstruction along on-site gravel roads could cause traffic flow concerns. Removal and replacement of recreation facilities and relocation of the Yreka Water Supply Pipeline would also increase traffic levels and could have construction traffic safety concerns associated with sharp curves. Cumulative projects that could also cause traffic flow and safety concerns include the widening of Copco Road by Siskiyou County Public Works, which currently does not have a date of implementation. The Proposed Action and the planned road widening could create significant cumulative traffic flow effects. The Proposed Action's incremental contribution to this significant cumulative effect would not be cumulatively considerable. The Lead Agencies would incorporate measures into the project to minimize such cumulative effects. Signage and construction traffic management would be implemented to maintain traffic flow. The Lead Agencies would coordinate with Siskiyou County Public Works to provide updates on the proposed deconstruction schedule and this could allow the planned Copco Road widening and other road improvements to be scheduled so as to help avoid cumulative effects. **The Proposed Action's incremental contribution to the significant cumulative traffic effects on on-site roads would not be cumulatively considerable.**

4.4.21.1.2 Traffic Safety Effects

Activities associated with the Proposed Action, would cause traffic safety effects associated with dust along gravel roads. High trip volumes would create a substantial amount of dust in dry conditions on Copco Road, Lakeview Road, Topsy Grade/Ager-Beswick Road, and the roads leading to and surrounding each dam. The dust could create a substantial visibility hazard for vehicles on the deconstruction sites throughout the area. Other future projects such as the planned subdivisions around Iron Gate Dam, mining activities, road improvements, and recreation could also increase dust along these roads and create significant cumulative dust impacts. The Proposed Action's contribution to the significant cumulative effects associated with dust would not be cumulatively considerable. The Proposed Action's dust impacts would be minimized with the incorporation of dust abatement measures. Additionally, the dust impacts would only last the duration of construction; no long term dust impacts would occur. **The Proposed Action's incremental contribution to the significant cumulative effects associated with dust from construction traffic would not be cumulatively considerable.**

Activities associated with the Proposed Action, would cause traffic safety effects associated with vehicle turnouts along Copco Road, Topsy Grade/Ager-Beswick Road and OR66. Slow moving construction traffic associated with the Proposed Action could have safety impacts when turning onto roads or merging onto freeways. A significant cumulative effect could occur if additional construction traffic was also present for roadway improvements, or if mining or other activities required the use of large construction vehicles in the same vicinity as the Proposed Action. The Proposed Action's incremental contribution to the cumulative effects would not be cumulatively considerable. The Proposed Action would implement appropriate signage and would coordinate with local agencies regarding road use during deconstruction to minimize cumulative effects. If conflicts are identified, the Lead Agencies would work with local agencies to re-route traffic, whenever feasible. **The Proposed Action's incremental contribution to the significant cumulative traffic effects associated with vehicle turnouts would not be cumulatively considerable.**

Activities associated with the Proposed Action would cause traffic safety effects associated with sharp curves along Copco Road and OR66. Activities associated with relocation of the Yreka's Water Supply Pipeline, implementation of the IMs, and relocation or demolition of recreation facilities would cause traffic safety effects associated with sharp curves along Copco Road and OR66. Sharp curves along Copco Road and OR66 could pose a safety risk for deconstruction traffic. All other projects using Copco Road or OR66 would be responsible for ensuring their own traffic safety; **therefore no significant cumulative effects are expected.**

4.4.21.1.3 Road Condition Effects

Under the Proposed Action, further analysis of road conditions and bridge weight capacities would be necessary. Bridges used for the Proposed Action deconstruction activities may not be capable of handling the heavy deconstruction vehicles. This impact is related solely to the Proposed Action; no other actions could contribute to this effect. **There would be no significant cumulative effects on road conditions and bridge weight capacities.**

4.4.21.1.4 Public Transit Effects

Under the Proposed Action, the trip volumes and routes of material hauling and worker trips could affect regional transit service. There are small overlaps between minor haul routes and public transit routes during deconstruction. No other known projects/actions in the area of analysis would affect regional transit service. **There would be no significant cumulative effects on regional transit service.**

4.4.21.1.5 Non-motorized Transportation Effects

Under the Proposed Action, heavy vehicle traffic could cause non-motorized transportation effects. Cyclists and pedestrians could travel along Copco and Topsy Grade/Ager-Beswick Roads because of the recreational nature of the area. These pedestrians and cyclists would have to travel along the road itself, and could encounter safety hazards when sharing the road with large hauling vehicles, which could occupy much of the available road width, generate dust, or vary speeds around corners. This

impact is related solely to the Proposed Action; no other actions could contribute to this effect. **There would be no significant cumulative effect on non-motorized transportation.**

4.4.21.1.6 KBRA - Programmatic Measures

Construction activities associated with the KBRA programs involving construction could cause temporary traffic effects. While several of the KBRA actions and programs would likely generate construction traffic, specific locations and construction, operation, and maintenance details are not available. For the purposes of this analysis, it is assumed that significant cumulative traffic impacts would occur. The KBRA would implement best management practices and would coordinate with local agencies to minimize or reduce traffic impacts. **Therefore, the KBRA's incremental contribution to the cumulative effects on traffic would not be cumulatively considerable. Implementation of the KBRA will require future environmental compliance as appropriate.**

Operational activities associated with the Fisheries Reintroduction and Management Plans could result in temporary traffic effects associated with trap and haul activities. Haul trucks would be required to relocate anadromous fish species around Keno Impoundment/Lake Ewauna and Link River. Haul trucks may travel on OR66, US97, access roads, and on-site roads. Seasonal trap and haul operations would occur during periods of poor water quality. Hauling activities would occur after the peak traffic-generating period of facility removal because fish cannot access Keno Dam until after removal of the Four Facilities; however, some construction traffic associated with completing removal activities and reservoir restoration may occur at the same time as hauling operations.

Other general cumulative actions or projects that could also contribute to increased traffic on these roads include the new residential subdivisions approved for Siskiyou County, mining, agricultural activities, recreation, and road improvements such as those planned in Siskiyou County. Together, these actions could increase the amount of traffic on existing roads and could cause temporary significant cumulative traffic impacts.

The KBRA's contribution to any cumulative traffic effects would be temporary and minimal. Seasonal trap and haul operations would occur at Keno Dam, but only until water quality conditions no longer require it. While construction traffic related to dam removal and hauling operations, taken together, could increase the severity of the traffic effects, the combined traffic would likely still be less than the peak traffic during dam deconstruction. **The KBRA's incremental contribution to the significant cumulative effects associated with traffic would not be cumulatively considerable. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.**

4.4.21.2 Alternatives 3, 4, and 5

Alternatives 3, 4, and 5 would have similar cumulative traffic effects as those described for Alternative 2 because they would require construction vehicles and equipment. Alternative 5 may contribute to fewer cumulative traffic effects because it would require

the removal of only two Facilities and therefore less roads would be used by construction vehicles and equipment. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; **therefore there would be no cumulative effects associated with KBRA actions.**

4.4.21.3 Mitigation Measures

No mitigation measures are required, **therefore, there would be no cumulatively considerable effects.**

4.4.22 Noise and Vibration

Cumulative noise impacts could occur from a variety of sources near the Four Facilities. Traffic, recreational activities, mining, agricultural activities, firefighting activities, and timber harvesting could all contribute to the cumulative background noise. The timeframe for noise and vibration impacts is during construction (May 2019 to December 2020).

Table 4-24 presents a summary of the noise and vibration impacts described in Chapter 3. These impacts are then analyzed for cumulative effects below the table.

Table 4-24. Summary of Noise and Vibration Impacts from Chapter 3

Potential Impact	Alternatives	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Construction and deconstruction activities at the Four Facilities could cause a temporary increase in noise levels at Copco 1 Dam that could affect residents in the area.	1	NCFEC	None	NCFEC

Potential Impact	Alternatives	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Operational activities associated with the Fisheries Reintroduction and Management Plan could result in temporary increases in noise and vibration levels from vehicles associated with trap-and-haul activities.	2,3	S	NV-1: Noise and Vibration Control Plan	LTS

Key:

- 1 = No Action/No Project
- 2 = Full Facilities Removal of Four Dams Alternative (Proposed Action)
- 3 = Partial Facilities Removal of Four Dams Alternative
- 4 = Fish Passage at Four Dams Alternative
- 5 = Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative
- NCFEC = No Change From Existing Conditions
- B = Beneficial
- LTS = Less than Significant
- S = Significant
- N/A = Not Applicable

Actions or projects that could contribute to cumulative noise effects include construction of the approved new subdivisions around Iron Gate Dam in Siskiyou County (see Table 4-4). Other more general activities that could contribute cumulative noise effects include road improvement projects, increases in traffic from population growth, and recreation activities.

4.4.22.1 Alternative 2: Full Facilities Removal of Four Dams

4.4.22.1.1 Construction Equipment Noise and Vibration

Deconstruction activities associated with the Proposed Action could cause a temporary increase in noise levels at Copco 1 that could affect residents in the area. Reservoir restoration activities could result in short-term increases in noise levels in the vicinity of Copco 1. Construction activities would result in significant noise impacts at Copco 1 during daytime construction activities and nighttime construction activities after 10:00 p.m. Helicopters and other equipment noise from embankment restoration would cause a temporary significant noise impact on the residential areas near Copco Lake. Mitigation measures would be implemented to reduce noise levels, but these would not reduce levels below significance criteria and noise would still be noticeable. At this time, there are no other known projects or actions are would be implemented in the same time frame near Copco 1 Reservoir that would result in a new source of noise and could contribute to cumulative noise effects. However, future residential development, mining, agricultural or recreation activities, firefighting practices, road improvements, and increased traffic levels from population increases could contribute to increased noise levels at Copco 1. If these activities occurred around Copco 1, they could result in significant cumulative noise effects. The Proposed Action’s incremental contribution to

the significant cumulative noise effects would be cumulatively considerable. The Proposed Action would implement all feasible mitigation measures to reduce noise levels (Mitigation Measure NV-1); however, noise would remain high for the duration of deconstruction. **Therefore, the Proposed Action’s incremental contribution to significant cumulative noise effects would be cumulatively considerable around Copco 1 for the duration of deconstruction. No other feasible mitigation measures are available to reduce these impacts; therefore they would remain cumulatively considerable.**

Deconstruction activities associated with the Proposed Action would cause a temporary increase in nighttime noise levels at Iron Gate Dam. Deconstruction noise would cause a temporary significant noise impact on the residential area near Iron Gate Dam at night. Helicopters and other equipment noise from embankment restoration would cause a temporary significant noise impact on the residential areas near Iron Gate Reservoir. Mitigation Measure NV-1 would be implemented but would not reduce nighttime outdoor noise impacts to less than significant levels at sensitive receptors. Several subdivisions have been approved around Iron Gate Dam in Siskiyou County, as noted above in Table 4-4. However, it is assumed that these construction activities associated with new subdivisions would not occur at night. No other cumulative actions have been identified that would result in increased nighttime noises around Iron Gate Dam. **There would be no significant cumulative nighttime noise effects at Iron Gate Dam during deconstruction.**

Blasting activities could increase vibration levels. Deconstruction activities could require some blasting to remove portions of the dams and associated infrastructure. Blasting would result in increased vibration levels around the Four Facilities.

Residential developments, increased traffic, mining, and recreation activities in the area around the dam sites could also cause increases in vibration. This could result in significant cumulative vibration impacts. However, the Proposed Action would implement measures to minimize or avoid vibration impacts (Mitigation Measure NV-1) and address potential vibration complaints. With these mitigation measures, the Proposed Action’s **incremental contribution to the significant cumulative effect associated with vibration would not be cumulatively considerable.**

4.4.22.1.2 Deconstruction-Related Traffic Noise

Transporting waste to off-site landfills and construction worker commutes could cause increases in noise along haul routes. Under the Proposed Action, transporting waste to off-site landfills and construction worker commutes could cause increases in noise along haul routes. The transporting of construction wastes, as well as the construction workers commuting to and from the deconstruction sites would increase traffic-related noise levels. Construction of new residential developments, traffic, mining, timber harvesting, agricultural activities, and recreation activities in the area around the dam sites could also cause increases in traffic-related noise. Traffic-related noise would therefore be a significant cumulative effect. The Proposed Action would have minor increases in noise levels 50 feet from all haul roads, and would be barely noticeable 500 feet away from

haul roads. Additionally, the traffic-related noise would only last the duration of construction; no long-term noise would occur after dam removal and restoration actions are complete. **The Proposed Action's incremental contribution to the significant cumulative effect associated with traffic-related noise would not be cumulatively considerable.**

4.4.22.1.3 KBRA - Programmatic Measures

Construction activities associated with the KBRA could cause temporary increases in noise and vibration levels. Several KBRA programs may cause noise and vibration impacts from the use of heavy equipment, including channel construction, mechanical thinning of trees, road decommissioning, fish passage and facilities construction, breaching levees, and fish hauling. These KBRA actions would take place in different locations around the Klamath Basin, and could occur at different times. While the locations, equipment, and schedules for the KBRA actions are currently not known, it is reasonable to assume that significant short-term cumulative noise and vibration effects could occur from implementation of the KBRA actions and other on-going activities such as traffic, timber harvesting, agricultural activities, mining, and recreation. The KBRA's incremental contribution to the significant cumulative noise and vibration impacts could be cumulatively considerable. Mitigation Measure NV-1 would be implemented, when appropriate, to reduce or avoid noise and vibration impacts. **Because the noise and vibration impacts would be temporary and would be reduced or avoided with mitigation, the KBRA's contribution to the significant short-term cumulative noise and vibration impacts would not be cumulatively considerable. Implementation of the KBRA will require future environmental compliance as appropriate.**

4.4.22.2 Alternatives 3, 4, and 5

Cumulative noise and vibration effects under Alternatives 3 and 5 would be similar to those described for Alternative 2 as they would require dam removal, blasting, and hauling of waste for disposal. Alternative 4 would not involve any dam removal or restoration activities and therefore would not contribute to any cumulative noise or vibration impacts associated with those activities. Alternative 4 would still contribute construction-related noise and vibration impacts from equipment and blasting during creation of fish passage facilities. KBRA cumulative effects under Alternative 3 would be similar to those described for the Proposed Action. The KBRA would not be implemented under Alternatives 4 and 5; **therefore there would be no cumulative effects associated with KBRA actions.**

4.4.22.3 Mitigation Measures

Noise impacts at Copco 1 and Iron Gate Dam would be cumulatively considerable under all alternatives with the exception of Iron Gate Dam under the Fish Passage at Four Dams Alternative. All feasible noise mitigation (Mitigation Measure NV-1) would be implemented to reduce noise during deconstruction; **however, noise impacts would remain cumulatively considerable at these locations for the duration of deconstruction and no further mitigation is possible.**

Chapter 5

Other Required Disclosures

Other required disclosures of environmental documents include irreversible and irretrievable commitment of resources, the relationship between short-term uses and long-term productivity, growth inducing impacts, summary of environmental impacts by alternative, significant and unavoidable impacts, preferred alternative, and the environmentally superior alternative.

5.1 Irreversible and Irretrievable Commitment of Resources

According to the National Environmental Policy Act (NEPA), an environmental impact statement (EIS) must contain a discussion of irreversible and irretrievable commitment of resources that would result from the Proposed Action if it was implemented (40 CFR Section 1502.16). The irreversible commitment of resources generally refers to the use or destruction of a resource that cannot be replaced or restored over a long period of time. The irretrievable commitment of resources refers to the loss of production or use of natural resources and represents lost opportunities for the period when the resource cannot be used. The California Environmental Quality Act (CEQA) also requires a discussion of any significant effect on the environment that would be irreversible if the project were implemented or would result in an irretrievable commitment of resources (CEQA Guidelines Section 15126(c)).

Dam removal, deconstruction, construction, and restoration activities under the Proposed Action and the Klamath Basin Restoration Agreement (KBRA) programs and plans would involve the consumption of nonrenewable natural resources. These nonrenewable natural resources would consist of petroleum for fuels necessary to operate equipment used during deconstruction activities. The Proposed Action would include removal of four dams and all power generation facilities. This would result in the generation of waste from the concrete, mechanical, and electrical items at the dams and power facilities. Petroleum fuels would be used to haul these materials to disposal sites in the project area. In addition to fuels used in transportation, the use of the disposal sites would constitute an irreversible and irretrievable commitment of resources. Concrete and earthen materials would be used as backfill to bury dam structures, backfill the excavated tailrace channels, and restore the river to its pre-dam appearance. These materials would be permanently committed during implementation of the Proposed Action. Construction activities necessary for implementation of KBRA programs and plans would require the use of nonrenewable natural resources including petroleum for fuels and other construction materials.

5.2 Relationship Between Short-term Uses and Long-term Productivity

As required by NEPA (40 CFR Section 1502.16), this section describes the relationship between short-term uses of the environment and the maintenance and enhancement of long-term productivity.

5.2.1 Klamath Hydroelectric Settlement Agreement

All four action alternatives involve demolition and/or construction activities including removing the dams and power generation facilities or constructing fish passage facilities. Dam removal (Under the Proposed Action, the Partial Facilities Removal Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative) and the construction of fish passage facilities (under the Fish Passage at Four Dams and Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternatives) would require short-term uses of capital, labor, fuels, and construction materials, as well as the creation of temporary new access roads and storage pads needed during deconstruction activities.

Removal of reservoirs at the Four Facilities under the Proposed Action, the Partial Facilities Removal Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative would benefit water quality by converting existing reservoir areas to a free-flowing river. Klamath Hydroelectric Project reservoirs have been shown to create higher water temperatures than those that would occur under natural conditions. Therefore, removal of the dams and return of the reservoirs to a natural flowing river would result in long-term beneficial effects on water temperature and overall water quality. In turn, improvements in water quality could result in improvements in scenic resources, such as water clarity or fish viewing opportunities. Further, removal of the reservoirs could result in beneficial effects on dissolved oxygen and pH levels in the water, thus increasing the likelihood of the free-flowing river consistently supporting beneficial uses. Other benefits to long-term productivity could result from decreases in the levels of microcystin and chlorophyll-*a* concentrations.

As described above, implementation of the Proposed Action would result in the drawdown and removal of reservoirs at the Four Facilities and would eliminate reservoir recreational opportunities at these sites. However, improved water quality as well as the return of the Klamath River to free-flowing river conditions would also result in benefits for other water-contact-based recreational opportunities, including recreational fishing and some whitewater boating. Removing the Four Facilities would result in the long-term loss power generating capacity and the associated long-term increases in green house gas emissions.

Long-term beneficial effects would also occur for aquatic resources under the Proposed Action, the Partial Facilities Removal Alternative, the Fish Passage at Four Dams Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative. Changed habitat conditions resulting from dam removal would reduce

impacts on salmonids from fish disease and parasites. Long-term changes to the flow regime of the Klamath River (under the Proposed Action and the Partial Facilities Removal Alternative) would benefit fall-run Chinook using the Lower Klamath River Reach. In addition, the absence of the dams would provide access to hundreds of miles of potential habitat in at least 49 tributaries upstream of Iron Gate Dam including Fall, Jenny, Shovel, and Spencer creeks, among others. Under the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative, flow increases would provide more habitat than under existing conditions for redband/rainbow trout and other resident riverine species, as well as any anadromous fish or lamprey that reestablish in the Hydroelectric Reach, but habitat gains would be less than under the Proposed Action. While removal of the two dams would eliminate existing habitat in Copco 1 and Iron Gate Reservoirs for adult shortnose and Lost River suckers, habitat within J.C. Boyle Reservoir would remain and higher flow releases would be made through the J.C. Boyle bypass reach than under existing conditions. Higher baseflows would also be provided in the Copco 2 bypass reach. These modifications would provide a benefit for fish living in this reach, including redband trout and anadromous fish. Dam removal would also restore habitat connectivity on the mainstem Klamath River and create additional habitat within the Hydroelectric Reach, thus increasing long-term productivity of coho and Chinook salmon, steelhead, and Pacific lamprey. Increases in fish populations would also result in beneficial effects for scenic fish viewing, recreational fishing, and conditions for species traditionally and culturally important to Indian Tribes.

Under the Fish Passage at Four Dams Alternative, long-term fishery productivity would increase in the basin due to water quality improvements from implementation of Oregon and California Total Maximum Daily Loads (TMDLs). Under this alternative, the hydrology of the Klamath River from Iron Gate Dam to the Klamath River Estuary would generally remain the same as existing conditions; however, fish would be able to migrate past the dams and would gain access to substantial areas of additional habitat. This access could still be delayed or impaired at the ladders, and continuing adverse water quality conditions in the reservoirs could also impair access to additional habitat. However, United States Department of the Interior (DOI) and United States Department of Commerce (DOC) prescriptions include elements to limit delays through reservoirs and fish ladders due to water quality issues. Implementation of fish passage at the dams under the Fish Passage at Four Dams Alternative would benefit anadromous fisheries in the Klamath River, thus resulting in long-term beneficial effects on recreational fishing.

Removal of dams and reservoirs under the Proposed Action, the Partial Facilities Removal Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative would result in gains in riparian habitat and wildlife corridors. The dams and reservoirs act as a barrier to terrestrial wildlife movement and migration. Elimination of the dams and reservoirs will remove these artificial barriers and allow for more natural gene-flow and population interactions.

Long-term beneficial effects on environmental justice populations would occur under the Proposed Action, the Partial Facilities Removal Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative. The tribes' heavy

reliance on social services and food subsidies is a direct result of long standing environmental injustices that have stripped tribal people of their ability to engage in long-standing traditions and subsistence and commercial harvest activities. Increases in the populations of Fall- and Spring-run Chinook salmon, coho salmon, and summer and winter steelhead would allow tribes to increase subsistence fishing and make fish a larger part of their diet and ceremonies. These effects would have long-term benefits on tribal health.

5.2.2 Klamath Basin Restoration Agreement

Implementation of some elements of the KBRA, including the Phase I Fisheries Restoration Plan, could result in short-term use of resources associated with standard construction activities. Implementation of KBRA actions would require short-term uses of capital, labor, fuels, and construction materials. Construction activities related to full implementation of the KBRA could result in short-term greenhouse gas emissions. The Climate Change Assessment and Adaptive Management Plan under the KBRA would assess and address potential climate change impacts in the region. The plans will assist the region in planning and responding to the climate change impacts identified in the EIS/Environmental Impact Report (EIR). The following paragraphs describe the long-term increases in fisheries productivity that would result from KBRA actions.

The Phase I and Phase II Fisheries Restoration Plan under the KBRA would accelerate long-term improvements to fine sediment, water temperature, nutrients, and dissolved oxygen, thus increasing long-term productivity of the Klamath Basin. Long-term productivity in the Klamath Basin would also occur due to the continuation of the Williamson River Delta Project, the Agency Lake and Barnes Ranches Projects, the Wood River Wetland Restoration, the Water Use Retirement Program (WURP), and the Interim Flow and Lake Level Program. In addition to long-term benefits to water quality, the KBRA elements would expand the habitats available to fish and terrestrial species throughout the basin and would increase their viability and resilience.

In addition, KBRA implementation would result in the establishment of limitations on specific diversions for Reclamation's Klamath Project to protect flows on the mainstem and provide specific allocations of water from Klamath Reclamation Project diversions to the wildlife refuges. These actions would result in long-term benefits to water quality and habitats in the project area. The ground water monitoring plan and pumping limits under the KBRA would also protect flows on the mainstem, thus providing stable habitat conditions to support the species of the basin. Additional aspects of the KBRA that would benefit aquatic resources include the WURP and the Fish Entrainment Reduction actions.

The Fisheries Restoration Plan phases I and II would result in long-term benefits to fisheries populations and abundance, and terrestrial wildlife. Wetland habitats would benefit over the long term due to increased supplies of water delivered to wildlife refuges in the basin.

Plans and programs in the KBRA including Wood River Wetland Restoration, Future Storage Opportunities, Water Management on Reclamation’s Klamath Project, and WURP could result in long-term beneficial effects on water supply and water rights. KBRA actions would improve water supply reliability and help ensure against impacts on water supply delivery. In addition, KBRA implementation would result in long-term benefits to surface water hydrology and flood protection related to new surface and ground water storage options. The WURP is intended to permanently increase the flow of water into Upper Klamath Lake by 30,000 acre feet per year (KBRA Section 16.2.2), and could include actions to increase inflow (including upland vegetation management) that would result in beneficial effects on ground water resources. The Interim Flow and Lake Level Program (KBRA Section 20.4) would result in similar beneficial effects on ground water.

Under the Power for Water Management Program of the KBRA, irrigators participating in the program would be eligible for adjusted power rates, which would continue to allow area farmers to pump water at electricity rates that would maintain profitability of their operations. This effect would benefit farm workers as it would help farm operators stay in business. Implementation of the Power for Water Management Program could also involve the development of renewable energy sources, which would provide green energy. This would be a beneficial effect. In addition, several elements of the KBRA are intended to restore fisheries and improve water quality. These programs, combined with the Klamath County Economic Development Plan (KBRA Section 27.3) and the Tribal Programs Economic Revitalization (KBRA Section 31) could improve social services for county residents and tribal members. The Mazama Forest Project (KBRA Section 33.2) would result in the acquisition of 90,000 acres of timberland to be managed by the Klamath Tribes’ Forest Management Plan, thus benefitting the Klamath Tribes.

KBRA programs including the Phase I Fisheries Restoration Plan, Fisheries Restoration Plan – Phase II, Williamson River Delta Project, Agency Lake and Barnes Ranches, Wood River Wetland Restoration, Flood Storage Opportunities, On-Project Plan, WURP, Fish Entrainment Reduction, and the Klamath Tribes Fishing Site would have long-term beneficial effects.

5.2.3 Keno Transfer

As a connected action to removal of the Four Facilities, PacifiCorp would transfer ownership and operational responsibility of the Keno facility to the DOI. The Proposed Action and Description of Alternatives, Chapter 2, describes that PacifiCorp would transfer ownership and operational responsibility of the Keno Facility to the DOI. Operations under DOI would be consistent with the historic operations of the facility in place since the existing contract was signed on January 4, 1968; therefore, there would be no changes to operations or the surrounding areas as a result of the transfer. Any future upgrades at the Keno Facility by DOI would be subject to additional environmental compliance.

Transfer of the Keno Facility may involve the use of vehicles and the commitment of vehicle fuel.

5.2.4 East and Westside Facilities – Programmatic Measure

The Proposed Action and the Partial Facilities Removal Alternative include the decommissioning of PacifiCorp’s East and Westside Facilities as a connected action to removal of the Four Facilities. In the event of an Affirmative Secretarial Determination, under a plan outlined in the Klamath Hydroelectric Settlement Agreement (KHSA), PacifiCorp would apply to Federal Energy Regulatory Commission (FERC) for a partial surrender of its license of the East and Westside Facilities in order to decommission the generating facilities (KHSA 6.4.1(A)). PacifiCorp would be responsible for the decommissioning and for recovering its costs through “standard ratemaking procedures” (KHSA 6.4.1(B)). Once the decommissioning was completed, the lands associated with the East and Westside Facilities would be transferred to DOI.

Removing the East and Westside Facilities would result in the long-term loss of power generating capacity and the associated long-term increases in green house gas emissions. Decommissioning may involve the use of vehicles and construction equipment. This would require short-term uses of capital, labor, fuels, and construction materials.

5.3 Growth Inducing Impacts

CEQA Guidelines Section 15126.2(d) requires an environmental document to:

“Discuss the ways in which the proposed project could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment. Included in this are projects which would remove obstacles to population growth....”

NEPA requires that an EIS analyze direct and indirect impacts of growth-inducing effects. Growth-inducing effects under NEPA are a subset of indirect effects, which are defined as effects that “are caused by the action and occur later in time or are farther removed in distance, but are still reasonably foreseeable” (40 CFR 1508.8(b)). Direct growth-inducing impacts generally stem from the construction of new housing, businesses, or infrastructure. Indirect growth inducement could result if a project establishes substantial new permanent employment opportunities or if it would remove obstacles hindering population growth, such as the expansion or the provision of urban services and infrastructure in an undeveloped area. Under CEQA, growth inducement may not necessarily be considered detrimental, beneficial, or of insignificant consequence. Induced growth is considered a significant impact only if it directly (or indirectly) affects the ability of agencies to provide needed public services, or if it can be demonstrated that the potential growth significantly affects the environment.

The Proposed Action and alternatives would not result in the construction of new housing either directly or indirectly. The Proposed Action and alternatives would not provide new water, wastewater, sewer, electricity, or natural gas infrastructure or facilities and would not require or create any new public services such as schools, public services, or public roads that could support increased growth in the Klamath Basin.

The Proposed Action and alternatives would require construction workers to perform the necessary construction work. Any employment required for the alternatives would be temporary and would be needed only during a 20-month period which includes an 8-month period of site preparation and partial drawdown at Copco 1 and a 12-month period for full drawdown and removal of facilities. Construction workers would likely commute to the sites from the surrounding local communities or find temporary accommodations for the duration of construction. Section 3.17, Population and Housing, analyzed all potential impacts from non-local workers as being less than significant as counties in the region have sufficient housing supply to accommodate the estimated number of non-local workers. Thus, there would be no need for the construction of new housing. Implementation of the Proposed Action or alternatives would not generate any permanent employment opportunities that would attract a substantial number of people to the region.

Restoration of the Klamath River fisheries is one of the main objectives of this project. If the fish populations were to rebound back to pre-dam levels, this could result in an increase in recreational fishing in the region, and possibly an increase in overall tourism. Such a change in visitor numbers would likely occur slowly as fish populations rebound, but would be unlikely to result in permanent population growth.

Neither the Proposed Action nor any of the alternatives would result in new housing, utilities, services, or permanent employment that could induce growth in the region, nor would the project result in any impacts that would require the provision of new housing, utilities, services, or permanent employment. The Proposed Action and alternatives would not induce growth.

5.4 Summary of Environmental Impacts

A summary of the environmental impacts identified for each alternative (including beneficial effects) is presented in Table 5-1 and Table 5-2. Table 5-1 presents impacts pursuant to both CEQA and NEPA; while Table 5-2 presents a summary of the environmental impacts for the resources analyzed in this EIS/EIR specific to only NEPA including Tribal Trust, Socioeconomics, and Environmental Justice.

For clarity, the Lead Agencies have updated the Final EIS/EIR in Tables 5-1 and 5-2 to indicate whether the effects described would be short term, long term or both, and to indicate when the effect described was analyzed at a programmatic level.

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
3.2 Water Quality				
Water Temperature				
Upper Klamath Basin (in the Hydroelectric Reach)				
Continued impoundment of water in the reservoirs could cause short-term and long-term seasonal water temperatures that are shifted from the natural thermal regime of the river and do not meet applicable Oregon DEQ and California Basin Plan water quality objectives and adversely affect beneficial uses in the Hydroelectric Reach.	1	NCFEC	None	NCFEC
Dam removal and/or reduction or elimination of hydropower peaking operations at J.C. Boyle Powerhouse could cause short-term and long-term alterations in daily water temperatures and diel temperature variation in the J.C. Boyle Bypass and peaking reaches.	2, 3, 4, 5	LTS - (short term ¹ and long term ²) for J.C. Boyle Bypass Reach in summer/fall B - (short term and long term) for J.C. Dam removal and conversion of the reservoir areas to a free-flowing river could cause short-term and long-term increases in spring time water temperatures and decreases in late summer/fall water temperatures in the Hydroelectric Reach downstream from Copco 1 Reservoir.	2, 3, 5	LTS - (short term and long term) for springtime B - (short term and long term) for late summer/fall	None	LTS - (short term and long term) for springtime B - (short term and long term) for late summer/fall

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Lower Klamath Basin				
Draining the reservoirs and release of sediment could cause short-term and long-term increases in sediment deposition in the Klamath River or Estuary that could alter morphological characteristics and indirectly affect seasonal water temperatures.	2, 3, 5	NCFEC ³	None	NCFEC
Continued impoundment of water in the reservoirs could cause short-term and long-term seasonal water temperatures that are shifted from the natural thermal regime of the river and do not meet applicable California North Coast Basin Plan water quality objectives and adversely affect beneficial uses in the Klamath River downstream from Iron Gate Dam.	1, 4	NCFEC	None	NCFEC
Dam removal and conversion of the reservoir areas to a free flowing river could result in short-term and long-term increases in spring water temperatures and decreases in late summer/fall water temperatures in the Lower Klamath River.	2, 3, 5	LTS – (short term and long term) Iron Gate Dam to Salmon River for springtime B – (short term and long term) in late summer/fall NCFEC – Klamath River downstream from Salmon River, the Klamath Estuary, and marine near shore environment	None	LTS – (short term and long term) Iron Gate Dam to Salmon River for springtime B – (short term and long term) in late summer/fall NCFEC – Klamath River downstream from Salmon River, the Klamath Estuary, and marine near shore environment
Suspended Sediments				
Upper Klamath Basin				
Continued impoundment of water in the reservoirs could result in short-term and long-term interception and retention of mineral (inorganic) suspended material by the Klamath Hydroelectric Project dams.	1, 4	NCFEC	None	NCFEC

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Implementation of IM 7, J.C. Boyle Gravel Placement and/or Habitat Enhancement, could result in short- term increases in mineral (inorganic) suspended material in the Hydroelectric Reach.	1 ,2 ,3	LTS (short term)	None	LTS (short term)
Implementation of IM 8, J.C. Boyle Bypass Barrier Removal, could result in short-term increases in mineral suspended material in the Hydroelectric Reach due to deconstruction activities.	1	LTS (short term)	None	LTS (short term)
Implementation of IM 16, Water Diversions, could result in short-term increases in mineral (inorganic) suspended material in the Hydroelectric Reach due to diversion screening deconstruction and construction activities.	2, 3	LTS (short term)	None	LTS (short term)
Continued impoundment of water in the reservoirs could cause short- term and long-term seasonal (April through October) increases in algal-derived (organic) suspended material in the Hydroelectric Reach due to in-reservoir algal blooms.	1, 4	NCFEC	None	NCFEC
Draining the reservoirs and release of sediment could cause short-term increases in suspended material in the Hydroelectric Reach downstream from J.C. Boyle Dam.	2, 3, 5	S (short term)	None	S (short term)
Construction/deconstruction activities could cause short-term increases in suspended material in the Hydroelectric Reach due to stormwater runoff from construction/deconstruction areas.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
Construction/deconstruction activities would include the demolition of various recreation facilities which could cause short-term increases in suspended material in the Hydroelectric Reach from stormwater runoff from the demolition areas.	2, 3, 5	LTS (short term)	None	LTS (short term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Revegetation associated with management of the reservoir footprint area after dam removal could decrease the short-term erosion of fine sediments from exposed reservoir terraces in the Hydroelectric Reach.	2, 3, 5	B (short term)	None	B (short term)
Dam removal could eliminate the interception and retention of mineral (inorganic) suspended material behind the dams and result in long-term increases in suspended material in the Hydroelectric Reach.	2, 3, 5	LTS (long term)	None	LTS (long term)
Dam removal could eliminate the interception and retention of algal-derived (organic) suspended material behind the dams and result in slight long-term increases in suspended material in the Hydroelectric Reach.	2, 3, 5	LTS (long term)	None	LTS (long term)
Lower Klamath Basin				
Draining the reservoirs and release of sediment could cause short-term increases in suspended material in the lower Klamath River and the Klamath Estuary.	2, 3, 5	S (short term)	None	S (short term)
Draining the reservoirs and release of sediment could cause short-term increases in sediment loads from the Klamath River to the Pacific Ocean and corresponding increases in concentrations of suspended material and rates of deposition in the marine nearshore environment.	2, 3, 5	LTS (short term)	None	LTS (short term)
Continued impoundment of water in the reservoirs could cause short-term and long-term interception and retention of mineral (inorganic) sediments by the dams and correspondingly low levels of suspended material immediately downstream from Iron Gate Dam.	1, 4	NCFEC	None	NCFEC
Continued impoundment of water in the reservoirs could result in short-term and long-term seasonal (April through October) increases in algal-derived (organic) suspended material in the Klamath Hydroelectric Project reservoirs and subsequent transport into the Klamath River downstream from Iron Gate Dam.	1, 4	NCFEC	None	NCFEC

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA

<i>Dissolved Oxygen</i>				
Upper Klamath Basin				
Continued impoundment of water in the reservoirs could cause long-term seasonal and daily variability in dissolved oxygen concentrations in the Hydroelectric Reach, such that levels do not meet ODEQ and California North Coast Basin Plan water quality objectives and adversely affect beneficial uses.	1, 4	NCFEC	None	NCFEC
Draining the reservoirs and release of sediment could cause short-term increases in oxygen demand (Immediate Oxygen Demand [IOD] and Biological Oxygen Demand [BOD]) and reductions in dissolved oxygen in the Hydroelectric Reach downstream from J.C. Boyle Reservoir.	2, 3, 5	S (short term)	None	S (short term)
Dam removal and conversion of reservoir areas to free-flowing river conditions could cause long-term increases in dissolved oxygen, as well as increased daily variability in dissolved oxygen, in the Hydroelectric Reach.	2, 3, 5	B (long term)	None	B (long term)
Dam removal and conversion of reservoir areas to free-flowing river conditions could cause long-term slight decreases in daily variability in dissolved oxygen in the Hydroelectric Reach at State line.	2, 3	LTS (long term)	None	LTS (long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Lower Klamath Basin				
Continued impoundment of water at the Four Facilities could result in continued release of water with low dissolved oxygen concentrations from Iron Gate Dam into the Klamath River immediately downstream from the dam.	1, 4	NCFEC	None	NCFEC
Dam removal and sediment release could cause short-term increases in oxygen demand (Immediate Oxygen Demand [IOD] and Biological Oxygen Demand [BOD]) and reductions in dissolved oxygen in the lower Klamath River, the Klamath Estuary, and the marine nearshore environment.	2, 3, 5	S - (short term) lower Klamath River from Iron Gate Dam to Clear Creek NCFEC - Klamath Estuary or marine nearshore environment	None	S – (short term) lower Klamath River from Iron Gate Dam to Clear Creek NCFEC - Klamath Estuary or marine nearshore environment
Dam removal and conversion of reservoir areas to a free-flowing river could cause long-term increases in dissolved oxygen, as well as increased daily variability in dissolved oxygen, in the lower Klamath River, particularly for the reach immediately downstream from Iron Gate Dam.	2, 3, 5	B (long term)	None	B (long term)
pH				
Upper Klamath Basin				
Continued impoundment of water in the reservoirs could cause long-term elevated seasonal pH and daily variability in pH in the Hydroelectric Reach.	1, 4	NCFEC	None	NCFEC
Dam removal and conversion of the reservoir areas to a free-flowing river could cause short-term and long-term slight increases in pH and daily pH fluctuations in riverine reaches in the Hydroelectric Reach.	2, 3, 5	LTS (short term and long term)	None	LTS (short term and long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Dam removal and conversion of the reservoir areas to a free-flowing river could cause short-term and long-term decreases in high pH (> 9 pH units) and large (0.5–1.5 pH units) daily fluctuations in the free-flowing reaches of the river that replace Copco 1 and Iron Gate Reservoirs in the Hydroelectric Reach.	2, 3, 5	B (short term and long term)	None	B (short term and long term)
Lower Klamath Basin				
Continued impoundment of water in the reservoirs could cause long-term elevated seasonal pH and daily variability in pH in the lower Klamath River downstream from Iron Gate Dam.	1, 4	NCFEC	None	NCFEC
Dam removal and conversion of the reservoir areas to a free-flowing river could cause long-term summertime increases in pH in the lower Klamath River downstream from Iron Gate Dam.	2, 3, 5	LTS – (long term) Lower Klamath River from Iron Gate Dam to confluence with the Scott River NCFEC – Lower Klamath River downstream from the Scott River, the Klamath Estuary, and the marine nearshore environment	None	LTS – (long term) Lower Klamath River from Iron Gate Dam to confluence with the Scott River NCFEC – Lower Klamath River downstream from the Scott River, the Klamath Estuary, and the marine nearshore environment
Chlorophyll-a and Algal Toxins				
Upper Klamath Basin				
Continued impoundment of water in the reservoirs could support long-term growth conditions for toxin-producing nuisance algal species such as <i>M. aeruginosa</i> , resulting in high seasonal concentrations of chlorophyll-a and algal toxins (i.e., microcystin) in the Hydroelectric Reach.	1, 4	NCFEC	None	NCFEC

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Dam removal and conversion of the reservoir areas to a free-flowing river would cause short-term and long-term decreases in levels of chlorophyll-a and substantially reduce or eliminate algal toxins (i.e., microcystin) in the Hydroelectric Reach.	2, 3, 5	B (short term and long term)	None	B (short term and long term)
Lower Klamath Basin				
Continued impoundment of water in the reservoirs could support long-term growth conditions for toxin-producing nuisance algal species such as <i>M. aeruginosa</i> , resulting in high seasonal concentrations of chlorophyll-a and algal toxins (i.e., microcystin) transported into the Klamath River from downstream from Iron Gate Dam to the Klamath Estuary, and potentially to the marine nearshore environment.	1, 4	NCFEC	None	NCFEC
Dam removal and conversion of the reservoir areas to a free-flowing river would cause short-term and long-term decreases in levels of chlorophyll-a and substantially reduce or eliminate algal toxins (i.e., microcystin) in the lower Klamath River and the Klamath Estuary.	2, 3, 5	B (short term and long term)	None	B (short term and long term)
Inorganic and Organic Contaminants				
Upper Klamath Basin				
Continued impoundment of water in the reservoirs and associated interception and retention of sediments behind the dams could cause long-term low-level exposure to inorganic and organic contaminants for freshwater aquatic species in the Hydroelectric Reach.	1, 4, 5	NCFEC	None	NCFEC
Continued impoundment of water in the reservoirs and associated interception and retention of sediments behind the dams could cause long-term low-level exposure to inorganic and organic contaminants in the Hydroelectric Reach through human consumption of resident fish tissue.	1, 4, 5	NCFEC	None	NCFEC

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Draining the reservoirs and sediment release could cause short-term increases in concentrations of inorganic and organic contaminants and result in low-level exposure for freshwater aquatic species in the Hydroelectric Reach.	2, 3, 5	LTS (short term)	None	LTS (short term)
Draining the reservoirs and sediment release could cause short-term human exposure to contaminants from contact with deposited sediments on exposed reservoir terraces and river banks within the Hydroelectric Reach.	2, 3, 5	LTS (short term)	None	LTS (short term)
Construction/deconstruction activities could cause short-term increases in inorganic and organic contaminants from hazardous materials associated with construction and revegetation equipment in the Hydroelectric Reach.	2, 3, 5	LTS (short term)	None	LTS (short term)
Reservoir area restoration activities could include herbicide application which could cause short-term levels of organic contaminants in runoff that are toxic to aquatic biota in the Hydroelectric Reach.	2, 3, 5	LTS (short term)	None	LTS (short term)
Lower Klamath Basin				
Dam removal and sediment release could cause short-term and long-term increases in concentrations of inorganic and organic contaminants and result in low-level exposure for freshwater aquatic species in the lower Klamath River and the Klamath Estuary.	2, 3, 5	LTS (short term and long term)	None	LTS (short term and long term)
Draining the reservoirs and sediment release could cause short-term human exposure to contaminants from contact with deposited sediments on exposed downstream river terraces and downstream river banks following reservoir drawdown.	2, 3, 5	LTS (short term)	None	LTS (short term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Construction/deconstruction activities could cause short-term increases in suspended sediments and the potential for inorganic and organic contaminants from hazardous materials associated with construction equipment to be transported into the lower Klamath River, Klamath Estuary, and the marine nearshore environment.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
<i>Keno Transfer</i>				
Implementation of the Keno Transfer could cause adverse water quality effects.	2, 3	NCFEC	None	NCFEC
<i>East and Westside Facilities – Programmatic Measure</i>				
Decommissioning the East and Westside Facilities could result in slight decreases in ammonia levels in the Keno Impoundment/Lake Ewauna.	2, 3	B (long term)	None	B (long term)
<i>City of Yreka Water Supply Pipeline Relocation – Programmatic Measure</i>				
Removal of Iron Gate Dam would require relocation of the Yreka Water Supply Pipeline which could cause short-term increases in suspended material in the Hydroelectric Reach during the construction period.	2, 3, 5	LTS (short term)	None	LTS (short term)
<i>KBRA – Programmatic Measures</i>				
Implementation of the Phase I Fisheries Restoration Plan could result in short-term construction-related increases in suspended materials and long-term reductions in fine sediment inputs, reduced summer water temperatures, improved nutrient interception, and increased dissolved oxygen levels.	2, 3	LTS (short term) B (long term)	None	LTS (short term) B (long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Implementation of the Phase II Fisheries Restoration Plan under the KBRA (KBRA Section 10.2) would include a continuation of the same types of resource management actions as under Phase I along with provisions for adaptive management of these actions and would therefore have the same short-term (i.e., during construction activities) and long-term impacts as Phase I.	2, 3	LTS (short term) B (long term)	None	LTS (short term) B (long term)
Implementation of the trap and haul element of the Fisheries Reintroduction and Management Plan could affect water quality during construction.	2, 3	LTS (short term)	None	LTS (short term)
Implementation of Wood River Wetland Restoration could result in short-term construction-related increases in suspended materials and long-term warmer spring water temperatures and reduced fine sediment and nutrient inputs to Upper Klamath Lake.	2, 3	LTS (short term) B (long term)	None	LTS (short term) B (long term)
Implementation of Water Diversion Limitations could result in decreased summer water temperatures in the Klamath River upstream of the Hydroelectric Reach.	2, 3	NCFEC (short term) B (long term)	None	NCFEC (short term) B (long term)
Implementation of the Water Use Retirement Program could result in decreases in summer water temperature and nutrient inputs to Upper Klamath Lake.	2, 3	NCFEC (short term) B (long term)	None	NCFEC (short term) B (long term)
Implementation of the Interim Flow and Lake Level Program could result in decreases in summer water temperature and nutrient inputs to Upper Klamath Lake.	2, 3	NCFEC (short term) B (long term)	None	NCFEC (short term) B (long term)
Implementation of the Upper Klamath Lake and Keno Nutrient Reduction Program could result in long-term decreases in nutrient inputs, increases in seasonal dissolved oxygen, and decreases in concentrations of nuisance algal species in these water bodies.	2, 3	Not determined at this time	None	Not determined at this time

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
<i>Trap and Haul Operations – Programmatic Measure</i>				
Implementation of the trap and haul operations could affect water quality during construction.	4, 5	LTS (short term)	None	LTS (short term)
3.3 Aquatic Resources				
<i>Critical Habitat</i>				
Continued impoundment of water within the reservoirs could alter the water quality and habitat suitability within critical habitat.	1	NCFEC (short term and long term) coho, Bull Trout, Southern Resident Killer Whale, and Eulachon	None	NCFEC (short term and long term) coho, Bull Trout, Southern Resident Killer Whale, and Eulachon
	4	NCFEC (short term and long term) coho, Bull Trout, Southern Resident Killer Whale	None	NCFEC (short term and long term) coho, Bull Trout, Southern Resident Killer Whale
Reservoir drawdown associated with dam removal could alter the quality of critical habitat.	2, 3, 5	S (short term) coho LTS (short term and long term) Bull Trout and Southern Resident Killer Whale	None	S (short term)coho LTS (short term and long term) Bull Trout and Southern Resident Killer Whale

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
The removal of dams and reservoirs could alter the availability and quality of critical habitat.	2, 3	B (long term) coho and eulachon LTS (short term and long term) Bull Trout and Southern Resident Killer Whale	None	B (long term) coho and eulachon LTS (short term and long term) Bull Trout and Southern Resident Killer Whale

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Fish passage provisions could result in alterations in habitat availability which could affect coho salmon.	4	B – (short term and long term) Upper Klamath River population unit NCFEC Mid-Klamath River, Shasta River, Scott River, Salmon River, three Trinity River, and Lower Klamath River population units)	None	B - (short term and long term) Upper Klamath River population unit NCFEC Mid-Klamath River, Shasta River, Scott River, Salmon River, three Trinity River, and Lower Klamath River population units
<i>Steelhead</i>				
Continued impoundment of water within the reservoirs could alter habitat suitability affecting steelhead.	1	NCFEC	None	NCFEC
Continued blockage of habitat access at the Four Facilities could alter habitat availability affecting steelhead.	1	NCFEC	None	NCFEC
Reservoir drawdown associated with dam removal could alter SSCs and bedload sediment transport and deposition and affect steelhead in the short term.	2, 3, 5	S (short term) summer and winter steelhead	AR-1: Protection of mainstem spawning AR-2: Protection of outmigrating juveniles AR-3: Fall flow pulses AR-4: Hatchery management	S (short term) summer and winter steelhead
Removal of Project dams could result in alterations in habitat availability, flow regime, water quality, temperature variation, and fish disease incidence, and algal toxins which could affect steelhead.	2, 3, 5	B (long term) summer and winter steelhead	None	B (long term) summer and winter steelhead
Fish passage provisions could result in alterations in habitat availability which could affect steelhead.	4	B (short term and long term)	None	B (short term and long term)
<i>Pacific Lamprey</i>				
Continued impoundment of water within the reservoirs could alter habitat suitability affecting Pacific lamprey.	1	NCFEC	None	NCFEC

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Continued blockage of habitat access at the Four Facilities could alter habitat availability affecting Pacific lamprey.	1	NCFEC	None	NCFEC
Reservoir drawdown associated with dam removal could alter SSCs, bedload sediment transport, and deposition which could affect Pacific lamprey in the short term.	2, 3, 5	S (short term)	AR-2: Protection of outmigrating juveniles AR-5: Pacific lamprey capture and relocation	S (short term)
Removal of Project dams could result in alterations in habitat availability, flow regime, water quality, and temperature variation, which could affect Pacific lamprey.	2, 3, 5	B (long term)	None	B (long term)
Fish passage provisions could result in alterations in habitat availability which could affect Pacific lamprey.	4	B (short term and long term)	None	B (short term and long term)
Green Sturgeon				
Continued impoundment of water within the reservoirs could alter habitat suitability affecting green sturgeon.	1	NCFEC	None	NCFEC
Continued blockage of habitat access at the Four Facilities could alter habitat availability affecting green sturgeon.	1	NCFEC	None	NCFEC
Reservoir drawdown associated with dam removal could alter SSCs and bedload sediment transport and deposition and affect green sturgeon.	2, 3, 5	S (short term)	AR-3: Fall flow pulses	S (short term)
Removal of dams could result in alterations in habitat availability, flow regime, water quality, temperature variation, fish disease incidence, and algal toxins which could affect green sturgeon.	2, 3, 5	LTS (long term)	None	LTS (long term)
Fish passage provisions could result in alterations in habitat availability which could affect green sturgeon.	4	NCFEC	None	NCFEC
Shortnose Sucker and Lost River				
Continued impoundment of water within the reservoirs could alter habitat suitability affecting Lost River and shortnose suckers.	1	NCFEC	None	NCFEC

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Continued blockage of habitat access at the Four Facilities could alter habitat availability affecting Lost River and shortnose suckers.	1	NCFEC	None	NCFEC
Reservoir removal associated with dam removal could alter habitat availability and affect Lost River and shortnose suckers	2, 3, 5	S (short term)	AR-6: Sucker rescue and relocation	LTS (short term)
Restoration action associated with KBRA implementation could alter habitat availability and suitability and affect Lost River and shortnose suckers.	2	B (long term)	None	B (long term)
Fish passage provisions could affect shortnose and Lost River Sucker populations by continuing poor water quality and high rates of predation.	4, 5	LTS (short term and long term)	None	LTS (short term and long term)
Redband Trout				
Continued impoundment of water within the reservoirs could alter habitat suitability affecting redband trout.	1	NCFEC	None	NCFEC
Continued blockage of habitat access at the Four Facilities could alter habitat availability affecting redband trout.	1	NCFEC	None	NCFEC
Reservoir drawdown associated with dam removal could alter SSCs and bedload sediment transport and deposition and affect redband trout.	2, 3, 5	LTS (short term)	None	LTS (short term)
Dam removal would restore connectivity among the lower basin, the Hydroelectric Reach and its tributaries, and the Upper Klamath Basin, and would rehabilitate and increase availability of riverine habitat within the Hydroelectric Reach.	2, 3, 5	B (long term)	None	B (long term)
Fish passage provisions could result in alterations in habitat availability which could affect redband trout.	4	B (short term and long term)	None	B (short term and long term)
Bull Trout				
Continued impoundment of water within the reservoirs and blockage of habitat could alter habitat suitability affecting bull trout.	1	NCFEC	None	NCFEC

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Dam removal and/or fish passage could alter habitat access for anadromous fish, which could affect bull trout.	2, 3, 4, 5	LTS (short term and long term)	None	LTS (short term and long term)
<i>Eulachon</i>				
Continued impoundment of water within the reservoirs and blockage of habitat could alter habitat suitability affecting eulachon.	1, 4	NCFEC	None	NCFEC
Reservoir drawdown associated with dam removal could alter SSCs and bedload sediment transport and deposition and affect eulachon.	2, 3, 5	LTS (long term)	None	LTS (long term)
<i>Longfin Smelt</i>				
Continued impoundment of water within the reservoirs and blockage of habitat could alter habitat suitability affecting longfin smelt.	1, 4	NCFEC	None	NCFEC
Reservoir drawdown associated with dam removal could alter SSCs and bedload sediment transport and deposition and affect longfin smelt.	2, 3, 5	LTS (short term and long term)	None	LTS (short term and long term)
<i>Introduced Resident Species</i>				
Continued impoundment of water within the reservoirs could alter habitat suitability affecting introduced resident species.	1, 4	NCFEC	None	NCFEC
Continued blockage of habitat access at the Four Facilities could alter habitat availability affecting introduced resident species.	1	NCFEC	None	NCFEC
Reservoir drawdown associated with dam removal would eliminate habitat for introduced resident species in the Hydroelectric Reach.	2, 3, 5	LTS ⁴ (long term)	None	LTS (long term)
Fish passage provisions could result in alterations in habitat availability which could affect introduced resident species.	4	NCFEC	None	NCFEC
<i>Freshwater mussels</i>				
Continued impoundment of water within the reservoirs and blockage of habitat could alter habitat suitability affecting freshwater mussels.	1	NCFEC	None	NCFEC

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Reservoir drawdown associated with dam removal could alter SSCs and bedload sediment transport and deposition and affect freshwater mussels in the short term.	2, 3, 5	S (short term)	AR-7: Freshwater mussel relocation	S (short term)
Dam removal would restore connectivity among the lower basin, the Hydroelectric Reach and its tributaries, and the Upper Klamath Basin, and would rehabilitate and increase availability of riverine habitat within the Hydroelectric Reach.	2, 3, 5	B (long term)	None	B (long term)
Continued impoundment of water within the reservoirs would result in no change in suspended sediments.	4	NCFEC	None	NCFEC
<i>Benthic Macroinvertebrates</i>				
Continued impoundment of water within the reservoirs and blockage of habitat could alter habitat suitability affecting macroinvertebrates.	1	NCFEC	None	NCFEC
Reservoir drawdown associated with dam removal could alter SSCs and bedload sediment transport and deposition and affect macroinvertebrates.	2, 3, 5	S (short term)	None	S (short term)
Dam removal would restore connectivity among the lower basin, the Hydroelectric Reach and its tributaries, and the Upper Klamath Basin, and would rehabilitate and increase availability of riverine habitat within the Hydroelectric Reach.	2, 3, 5	B (long term)	None	B (long term)
Fish passage provisions could result in alterations in habitat availability which could affect macroinvertebrates.	4	NCFEC	None	NCFEC

Deconstruction Impacts				
The removal of dams and reservoirs and the construction of fish passage facilities could disturb the river channel during construction which could affect aquatic species.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
Keno Transfer				
Implementation of the Keno Transfer could cause adverse aquatic resource effects.	2, 3	NCFEC	None	NCFEC
East and Westside Facilities – Programmatic Measure				
Decommissioning the East and Westside Facilities could cause adverse aquatic resource effects.	2, 3	NCFEC	None	NCFEC

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
<i>City of Yreka Water Supply Pipeline Relocation – Programmatic Measure</i>				
Removal of the dams will require the new construction to relocate of the City of Yreka Water Supply Pipeline. Relocation of the City of Yreka Water Supply Pipeline could disturb the river channel during construction and affect aquatic resources.	2, 3, 5	LTS (short term)	None	LTS (short term)
<i>KBRA – Programmatic Measures</i>				
Implementation of Phases I and 2 Fisheries Restoration Plans and Fisheries Monitoring Plan could result in alterations to water quantity, water quality, habitat availability and habitat quality, and affect aquatic species.	2, 3	B – (long term) fall-run Chinook salmon, spring-run Chinook salmon, steelhead, Pacific lamprey, redband trout, benthic macroinvertebrates, and shortnose and Lost River suckers, coho salmon except for the Trinity River Populations. LTS – (long term) coho salmon (Trinity River population unit) NCFEC - green sturgeon, bull trout, eulachon, Southern Resident Killer Whales, and freshwater mussels	None	B (long term)- fall-run Chinook salmon, spring-run Chinook salmon, steelhead, Pacific lamprey, redband trout, benthic macroinvertebrates, and shortnose and Lost River suckers, coho salmon except for the Trinity River Populations) LTS – (long term) coho salmon (Trinity River population unit) NCFEC - green sturgeon, bull trout, eulachon, Southern Resident Killer Whales, and freshwater mussels

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Implementation of Phase I of the Fisheries Reintroduction and Management Plan could result in alterations to habitat availability (fish access), and could affect aquatic species.	2, 3	B - (long term) fall-run Chinook salmon, spring-run Chinook salmon, steelhead, Pacific lamprey, Southern Resident Killer Whales, benthic macroinvertebrates, coho except those Trinity River population units; LTS - (long term) redband trout, shortnose and Lost River suckers NCFEC - coho Trinity River Population Units; green sturgeon, bull trout, eulachon, and freshwater mussels	None	B - (long term) fall-run Chinook salmon, spring-run Chinook salmon, steelhead, Pacific lamprey, Southern Resident Killer Whales, benthic macroinvertebrates, coho except those Trinity River population units LTS - (long term) redband trout, shortnose and Lost River suckers NCFEC - coho Trinity River Population Units; green sturgeon, bull trout, eulachon, and freshwater mussels

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Implementation of Water Diversion Limitations could result in reducing uncertainties associated with maintaining adequate ecological flows for aquatic species and their habitats, especially in low-flow years, and could alter water quality, and water temperatures in certain seasons and affect aquatic species.	2, 3	B - (long term) fall-run Chinook salmon, spring-run Chinook salmon, steelhead, Pacific lamprey, redband trout, shortnose and Lost River suckers, coho except those Trinity River population units NCFEC - coho Trinity River Population Units; green sturgeon, bull trout, eulachon, Southern Resident Killer Whales, freshwater mussels, and benthic macroinvertebrates	None	B - (long term) fall-run Chinook salmon, spring-run Chinook salmon, steelhead, Pacific lamprey, redband trout, shortnose and Lost River suckers, coho except those Trinity River population units NCFEC (coho Trinity River Population Units; green sturgeon, bull trout, eulachon, Southern Resident Killer Whales, freshwater mussels, and benthic macroinvertebrates

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Implementation of On-Project Plan could result in alterations to water quantity and water quality and affect aquatic species.	2, 3	B - (long term) fall-run Chinook salmon, spring-run Chinook salmon, steelhead, Pacific lamprey, redband trout, shortnose and Lost River suckers. Coho salmon, except those Trinity River population units NCFEC - coho Trinity River Population Units; green sturgeon, bull trout, eulachon, Southern Resident Killer Whales, freshwater mussels, and benthic macroinvertebrates	None	B - (long term) fall-run Chinook salmon, spring-run Chinook salmon, steelhead, Pacific lamprey, redband trout, shortnose and Lost River suckers. Coho salmon, except those Trinity River population units NCFEC - coho Trinity River Population Units; green sturgeon, bull trout, eulachon, Southern Resident Killer Whales, freshwater mussels, and benthic macroinvertebrates

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
The Water Use Retirement Program could alter water quantity and water quality, and affect aquatic species.	2, 3	B - (long term) fall-run Chinook salmon, spring-run Chinook salmon, steelhead, Pacific lamprey, redband trout, shortnose and Lost River suckers, coho except those Trinity River population units NCFEC - coho Trinity River Population Units; green sturgeon, bull trout, eulachon, Southern Resident Killer Whales, freshwater mussels, and benthic macroinvertebrates	None	B - (long term) fall-run Chinook salmon, spring-run Chinook salmon, steelhead, Pacific lamprey, redband trout, shortnose and Lost River suckers, coho except those Trinity River population units NCFEC - coho Trinity River Population Units; green sturgeon, bull trout, eulachon, Southern Resident Killer Whales, freshwater mussels, and benthic macroinvertebrates

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Implementation of the Fish Entrainment Reduction could result in alterations to potential alterations to mortality risk and affect aquatic species.	2, 3	B - (long term) shortnose and Lost River suckers, redband trout, fall-run Chinook salmon, spring-run Chinook salmon, steelhead, Pacific lamprey, and coho salmon from the Upper Klamath River population unit NCFEC - all other coho salmon population units, green sturgeon, bull trout, eulachon, Southern Resident Killer Whales, freshwater mussels, and benthic macroinvertebrates	None	B - (long term) shortnose and Lost River suckers, redband trout, fall-run Chinook salmon, spring-run Chinook salmon, steelhead, Pacific lamprey, and coho salmon from the Upper Klamath River population unit NCFEC - all other coho salmon population units, green sturgeon, bull trout, eulachon, Southern Resident Killer Whales, freshwater mussels, and benthic macroinvertebrates
Implementation of the Klamath Tribes Interim Fishing Site could result in alterations to managed harvest mortality of fish species that are culturally important to the Klamath River Tribes,	2, 3	NCFEC	None	NCFEC
Implementation of the Interim Flow and Lake Level Program could result in decreases in summer water temperature and nutrient inputs to Upper Klamath Lake.	2, 3	B (long term)	None	B (long term)
<i>Trap and Haul Operations – Programmatic Measure</i>				
Implementation of trap and haul measures could affect aquatic species.	4, 5	B – (long term) fall-run Chinook	None	B – (long term) fall-run Chinook

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
3.4 Algae				
<i>Upper Klamath Basin Upstream of the Influence of J.C. Boyle Reservoir</i>				
Dam removal activities could decrease the long-term spatial extent, temporal duration, toxicity, or concentration of nuisance and/or noxious phytoplankton in the area of analysis.	2, 3, 5	NCFEC	None	NCFEC
Dam removal activities could decrease the long-term spatial extent, temporal duration, or biomass of nuisance periphyton in the area of analysis.	2, 3, 5	NCFEC	None	NCFEC
<i>Hydroelectric Reach</i>				
Continued impoundment of water in the reservoirs could support long-term growth of nuisance and/or noxious phytoplankton blooms in the Hydroelectric Reach.	1, 4	NCFEC	None	NCFEC
Sediment release associated with dam removal could cause short-term increases in sediment-associated nutrients downstream from J.C. Boyle Dam that could stimulate nuisance and/or noxious phytoplankton growth in the Hydroelectric Reach.	2, 3	NCFEC	None	NCFEC
Removal of the reservoirs would eliminate lacustrine habitat behind the dams and could decrease or eliminate the long-term spatial extent, temporal duration, or concentration of nuisance and/or noxious phytoplankton blooms in the Hydroelectric Reach and subsequent transport to the Klamath River from downstream from Iron Gate Dam to the Klamath Estuary.	2, 3, 5	B (long term)	None	B (long term)
Sediment release associated with the Proposed Action could cause short-term increases in sediment-associated nutrients downstream from J.C. Boyle Dam that could stimulate nuisance periphyton growth in the Hydroelectric Reach.	2, 3	NCFEC	None	NCFEC

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Conversion of the reservoir areas to a free-flowing river, and the elimination of hydropower peaking operations could cause long-term increases in nutrient levels and biomass of nuisance periphyton in low-gradient channel margin areas within the Hydroelectric Reach downstream from J.C. Boyle Dam. ⁵	2, 3, 5 ⁶	S (long term)	None	S (long term)
Construction and deconstruction activities would include the demolition of various recreation facilities that could affect algae in the Hydroelectric Reach.	2, 3, 5	NCFEC	None	NCFEC
Increases in J.C. Boyle Dam flow releases and associated increases in summer and early fall water temperatures in the Bypass Reach (Section 3.2.4.3.4), as well as decreases in peaking flows and less flow and water temperature variation in the Peaking Reach, could result in small amounts of periphyton colonization in the Klamath River downstream from J.C. Boyle Dam and upstream of Copco 1 Dam.	4	LTS	None	LTS
Implementation of IM 7, J.C. Boyle Gravel Placement and/or Habitat Enhancement, could result in increased bedload mobility and increased scour of nuisance periphyton in the Hydroelectric Reach.	2	B (long term)	None	B (long term)
<i>Klamath River Downstream from Iron Gate Dam</i>				
Continued impoundment of water in the reservoirs could support long-term growth of seasonal nuisance and/or noxious phytoplankton blooms in the Hydroelectric Reach and subsequent transport into the Klamath River downstream from Iron Gate Dam.	1, 4	NCFEC	None	NCFEC
Continued impoundment of water at the Four Facilities could support long-term growth of nuisance periphyton such as Cladophora downstream from Iron Gate Dam.	1	NCFEC	None	NCFEC
	4	LTS (long term)	None	LTS (long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Removal of the reservoirs would eliminate lacustrine habitat behind the dams and could substantially reduce or eliminate the long-term transport of nuisance and/or noxious phytoplankton blooms and concentrations of algal toxins into the Klamath River downstream from Iron Gate Dam.	2, 3, 5	B (long term)	None	B (long term)
Dam removal and conversion of the reservoir areas to a free-flowing river could cause long-term increases in nutrient levels and biomass of nuisance periphyton in the Klamath River downstream from Iron Gate Dam.	2, 3, 5	LTS (long term)	None	LST (long term)
Construction and deconstruction activities would include the demolition of various recreation facilities that could affect algae downstream from Iron Gate Dam.	2, 3, 5	NCFEC	None	NCFEC
<i>Klamath Estuary</i>				
Continued impoundment of water in the reservoirs could support long-term growth of nuisance and/or noxious phytoplankton blooms in the Hydroelectric Reach and subsequent transport into the Klamath Estuary.	1, 4	NCFEC	None	NCFEC
Removal of the reservoirs would eliminate lacustrine habitat behind the dams could substantially reduce or eliminate the long-term transport of nuisance and/or noxious phytoplankton blooms and concentrations of algal toxins into the Klamath Estuary.	2, 3, 5	B (long term)	None	B (long term)
Dam removal and conversion of the reservoir areas to a free-flowing river could cause long-term increases in nutrient levels and periphyton biomass in the Klamath Estuary.	2, 3, 5	LTS (long term)	None	LTS (long term)
<i>Keno Transfer</i>				
Implementation of the Keno Transfer could cause adverse algae effects.	2, 3	NCFEC	None	NCFEC

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
<i>East and Westside Facilities – Programmatic Measure</i>				
Decommissioning the East and Westside Facilities could cause adverse algae effects.	2, 3	NCFEC	None	NCFEC
<i>City of Yreka Water Supply Pipeline Relocation - Programmatic Measure</i>				
Relocation of the Yreka Water Supply Pipeline, required as part of the removal of Iron Gate Dam, could affect algae.	2, 3, 5	NCFEC	None	NCFEC
<i>KBRA – Programmatic Measures</i>				
Implementation of restoration actions, programs, and/or plans presented in the KBRA would accelerate restoration actions currently underway throughout the Klamath Basin and reduce nuisance and/or noxious phytoplankton blooms through their beneficial effects on flow and water quality.	2, 3	B (long term)	None	B (long term)
Implementation of the Phase I Fisheries Restoration Plan could result in a long-term reduction in nutrients and associated decreases in nuisance and/or noxious phytoplankton and periphyton blooms.	2, 3	B (long term)	None	B (long term)
Implementation of the Phase II Fisheries Restoration Plan under the KBRA (KBRA Section 10.2) would include a continuation of the same types of resource management actions as under Phase I along with provisions for adaptive management of these actions and would therefore have the same impacts as Phase I.	2, 3	B (long term)	None	B (long term)
Implementation of Wood River Wetland Restoration could result in reduced nutrient inputs to Upper Klamath Lake and associated decreases in nuisance and/or noxious phytoplankton blooms.	2, 3	B (long term)	None	B (long term)
Implementation of the Water Use Retirement Program could result in decreases in nutrient inputs to Upper Klamath Lake and associated decreases in nuisance and/or noxious phytoplankton blooms.	2, 3	B (long term)	None	B (long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Implementation of the Interim Flow and Lake Level Program could result in decreases in nutrient inputs to Upper Klamath Lake and associated decreases in nuisance and/or noxious phytoplankton blooms.	2, 3	B (long term)	None	B (long term)
Implementation of the Upper Klamath Lake and Keno Nutrient Reduction Program could result in decreases in nutrient inputs to Upper Klamath Lake and Keno Impoundment/Lake Ewauna and associated decreases in nuisance and/or noxious phytoplankton blooms.	2, 3	N/A'	N/A	N/A
3.5 Terrestrial Resources				
Continued impoundment of water in the reservoirs could result in the continuance of various stressors in the area of analysis including habitat degradation, invasive species, barriers to movement of some terrestrial wildlife species, and uncertainties in water deliveries to the NWRs.	1	NCFEC	None	NCFEC
Construction activities could result in the loss of wetland and riparian vegetation communities and culturally important species including willows.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
Construction activities could result in direct mortality or harm to special-status invertebrate, amphibian and reptile species during construction.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
Construction activities could result in nest abandonment by birds, including special-status bird species, during construction.	2, 3, 4, 5	LTS (short term)	TER-2: Nesting Bird Surveys TER-3: Bald and Golden Eagle Surveys	LTS (short term)
Construction activities could result in on the loss of special-status plants.	2, 3, 4, 5	LTS (short term)	TER-1: Habitat Rehabilitation Plan TER-4: Surveys for Special Status Plants	LTS (short term)
Construction activities could result in adverse impacts on wildlife from riparian habitat loss.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
Removal of reservoirs and associated loss of habitat could result in impacts on wildlife.	2, 3, 5	LTS (long term)	None	LTS (long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Dam removal and the flushing of sediments could result in long-term impacts on riparian habitat from sedimentation in downstream reaches.	2, 3, 5	LTS (long term)	None	LTS (long term)
Removal of reservoirs could result in loss of reservoir wetlands.	2, 3, 5	S (long term)	TER-5: Permanent Loss of Wetlands at Reservoirs	LTS (long term)
Construction activities could result in the removal of trees and other vegetation and could result in long-term impacts on wildlife habitat, particularly for nesting birds.	2, 3, 4, 5	LTS (long term)	TER-1: Habitat Rehabilitation Plan TER-2: Nesting Bird Surveys TER-3: Bald and Golden Eagle Surveys	LTS (long term)
Removal of dam facilities could result in long-term impacts on bats from loss of roosting habitat.	2, 3, 5	S (long term)	TER-6: Impacts on Special-Status Bats from Loss of Roosting Habitat	LTS (long term)
Dam removal and the flushing of sediments could result in long-term impacts on amphibians from changes in habitat due to sedimentation in downstream reaches.	2, 3, 5	LTS (long term)	None	LTS (long term)
Removal of the reservoirs could result in long-term impacts on special-status species from loss of aquatic habitat at reservoirs.	2, 3, 5	LTS (long term) Special Status Birds LTS (long term) Special-status plants at the reservoirs	TER-2: Nesting Bird Surveys TER-3: Bald and Golden Eagle TER-4: Surveys for Special Status Plants	LTS (long term)
Dam removal and associated sedimentation in downstream reaches could result in impacts on culturally important species.	2, 3, 5	LTS (short term)	None	LTS (short term)
Removal of reservoirs and associated facilities could result in long-term impacts on wildlife corridors.	2	B (long term)	None	B (long term)
Continued existence of the reservoirs and/or other facilities could present a barrier to movement of some terrestrial species.	1, 3, 4, 5	NCFEC	None	NCFEC
Exposed reservoir bottoms and other areas of construction disturbance could result in impacts from invasive plants.	2, 3, 4, 5	LTS (short term)	TER-1: Habitat Rehabilitation Plan	LTS (short term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Removal of various recreation facilities could result in impacts to terrestrial resources during construction.	2, 3, 5	LTS (short term)	TER-1: Habitat Rehabilitation Plan TER-2: Nesting Bird Surveys TER-3: Surveys for Special Status Plants TER-4: Surveys for Special Status Plants	LTS (short term)
<i>Keno Transfer</i>				
Implementation of the Keno Transfer could cause impacts to terrestrial resources.	2, 3	NCFEC	None	NCFEC
<i>East and Westside Facilities - Programmatic Measure</i>				
Decommissioning the East and Westside Facilities could cause adverse effects to terrestrial resources.	2, 3	NCFEC	None	NCFEC
<i>City of Yreka Water Supply Pipeline Relocation - Programmatic Measure</i>				
Removal of Iron Gate Dam would require relocation of the Yreka Water Supply Pipeline which could result in impacts on terrestrial resources from construction activities and pipe alignment.	2, 3, 5	LTS (short term)	TER-1: Habitat Rehabilitation Plan TER-2: Nesting Bird Surveys TER-3: Surveys for Special Status Plants TER-4: Surveys for Special Status Plants	LTS (short term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
<i>KBRA - Programmatic Measures</i>				
Construction activities associated with the Fisheries Restoration Plan- Phase I and Phase II could result in impacts on terrestrial wildlife and/or habitat.	2,3	S (short term)	TER-1: Habitat Rehabilitation Plan TER-2: Nesting Bird Surveys TER-3: Surveys for Special-Status Plants TER-4: Permanent Loss of Wetlands at Reservoirs	LTS (short term)
Construction activities associated with Fish Entrainment Reduction could result in impacts on terrestrial wildlife and/or habitat	2,3	S (short term)	TER-1: Habitat Rehabilitation Plan TER-2: Nesting Bird Surveys TER-3: Surveys for Special-Status Plants TER-4: Permanent Loss of Wetlands at Reservoirs	LTS (short term)
Modification of aquatic habitat from the Wood River Wetland Restoration project could result in impacts on terrestrial wildlife and/or habitat.	2,3	LTS (long term)	None	LTS (long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
The Water Diversion Limitations, On-Project Plan, WURP, and Interim Flow and Lake Level Programs could result in impacts on terrestrial wildlife and/or habitat.	2,3	B – (long term) Lower Klamath NWR, Tule Lake NWR	TER-2: Nesting Bird Surveys	B (long term)
		LTS – (long term) Upper Klamath NWR (waterfowl and non-game waterbirds) S – (long term) Upper Klamath NWR (juniper removal actions and effects on terrestrial wildlife including nesting migratory birds)		LTS (long term)
The Mazama Forest Project could result in adverse impacts on terrestrial resources.	2,3	NCFEC	None	NCFEC
3.6 Flood Hydrology				
Continued operation of the Klamath Hydroelectric Project and Reclamation's Klamath Project could alter river flows and result in changes to flood risks.	1	NCFEC	None	NCFEC
Ongoing restoration actions could affect flood hydrology.	1	NCFEC	None	NCFEC
Dam failure could inundate areas in the downstream watershed.	1	LTS (long term)	None	LTS (long term)
Drawdown of reservoirs could result in short-term increases in downstream surface water flows and could result in changes to flood risk.	2, 3, 5	LTS (short term)	None	LTS (short term)
Reservoir drawdown and resulting downstream sediment deposition could change flood risk.	2, 3, 5	LTS (short term)	None	LTS (short term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Changes in flows following dam removal could result in changes to the 100-year floodplain downstream from Iron Gate Dam between River Mile 190 and 171.	2, 3, 5	S (long term)	H-1: Emergency Response Plan H -2: Move or Relocate Structures	LTS (long term)
Removing the Four Facilities could reduce the risks associated with a dam failure.	2	B (long term)	None	B (long term)
Removing Copco 1 and Iron Gate Dams could reduce the risks associated with a dam failure.	5	B (long term)	None	B (long term)
Removal of recreation facilities located on the banks of the existing reservoirs which could affect flood hydrology.	2, 3, 5	NCFEC	None	NCFEC
Changes in flows in the Hydroelectric Reach including the J.C. Boyle and Copco 2 Bypass Reaches could affect flood hydrology.	4, 5	LTS (long term)	None	LTS (long term)
Construction of a new gage within the 100-year floodplain at Copco 2 Dam or J.C. Boyle Dam to measure flows could affect flood hydrology.	5	LTS (long term)	None	LTS (long term)
<i>Keno Transfer</i>				
Implementation of the Keno Transfer could cause changes to operations affecting flows downstream from Keno Dam, which could cause changes to flood risks.	2, 3	NCFEC	None	NCFEC
<i>East and Westside Facilities - Programmatic Measure</i>				
Decommissioning the East and Westside Facilities could cause changed in flood risk downstream from the facilities.	2, 3	NCFEC	None	NCFEC
<i>City of Yreka Water Supply Pipeline Relocation – Programmatic Measure</i>				
Removal of Iron Gate Dam would require relocation of the Yreka Water Supply Pipeline which could affect flood risk.	2, 3, 5	NCFEC	None	NCFEC

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
<i>KBRA - Programmatic Measures</i>				
Implementation of the Fisheries Restoration Plans could change flows downstream from Upper Klamath Lake, which could result in changes to flood risks	2, 3	LTS (long term)	None	LTS (long term)
Implementation of Wood River Wetland Restoration by the Bureau of Land Management may change flows upstream and downstream from Upper Klamath Lake, which could result in changes to flood risks.	2, 3	B (long term)	None	B (long term)
Implementation of Future Storage Opportunities by Reclamation may cause changes to flows upstream and down downstream from Upper Klamath Lake, which could result in changes to flood risks	2, 3	B (long term)	None	B (long term)
Implementation of the On-Project Plan may change flows downstream from Upper Klamath Lake during dry years, which could result in changes to flood risks.	2, 3	NCFEC	None	NCFEC
Implementation of the WURP would change flows upstream of Upper Klamath Lake, which could result in changes to flood risks.	2, 3	NCFEC	None	NCFEC
Implementation of an Emergency Response Plan could result in changes to flood risks in the event of failure to a Klamath Reclamation Project facility or dike on Upper Klamath Lake or Lake Ewauna.	2, 3	NCFEC	None	NCFEC
Implementation of Climate Change Assessment and Adaptive Management may change flows upstream and downstream from Upper Klamath Lake, which could result in changes to flood risks.	2, 3	B (long term)	None	B (long term)
Implementation of Interim Flow and Lake Program during the interim period would change river flows, which could result in changes to flood risks.	2, 3	NCFEC	None	NCFEC

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
3.7 Ground Water				
Continued impoundment of water in the reservoirs with no changes in facility operations could result in impacts on ground water resources in the vicinity of the reservoirs.	1, 4	NCFEC	None	NCFEC
Continued impoundment of the water in the reservoirs could lead to increased ground water storage.	1, 4, 5	B (long term)	None	B (long term)
Draining of the reservoirs could lower ground water levels in the aquifer adjacent to the reservoirs, which could impact existing wells.	2, 3, 5	S (long term)	GW-1: Deepening or Replacement of an Existing Affected Ground Water Well	LTS (long term)
Removing the dams and eliminating the reservoirs could reduce ground water discharge to the Klamath River.	2, 3, 5	LTS (long term)	None	LTS (long term)
Dam removal activities would include the demolition of various recreation facilities which could affect ground water.	2, 3, 5	NCFEC	None	NCFEC
Keno Transfer				
Implementation of the Keno Transfer could cause adverse effects to local ground water.	2, 3	NCFEC	None	NCFEC
East and Westside Facilities – Programmatic Measure				
Decommissioning the East and Westside Facilities could have adverse effects to ground water resources.	2, 3	NCFEC	None	NCFEC
City of Yreka Water Supply Pipeline Relocation – Programmatic Measure				
Removal of Iron Gate Dam would require relocation of the Yreka Water Supply Pipeline which could affect ground water.	2, 3, 5	NCFEC	None	NCFEC
KBRA – Programmatic Measures				
The Water Diversion Limitations program could reduce irrigation water in the driest years.	2,3	B (long term)	None	B (long term)
Upland vegetation management under the WURP would increase inflow to Upper Klamath Lake.	2,3	B (long term)	None	B (long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
The purchase and lease of water under the Interim Flow and Lake Level Program would increase water for fisheries.	2,3	LTS (short term) B (long term)	None	LTS (short term) B (long term)
Implementation of an Emergency Response Plan could result in changes to ground water following the failure of a Klamath Reclamation Project facility or dike on Upper Klamath Lake or Lake Ewauna.	2,3	NCFEC – ground water resources B (long term) – reduction in ground water use	None	NCFEC - ground water resources B (long term) – reduction in ground water use
3.8 Water Supply/Water Rights				
Continued operation of the Four Facilities could affect water supply operations.	1, 4	NCFEC	None	NCFEC
Ongoing restoration actions would continue to be implemented and could affect water supply availability.	1	NCFEC	None	NCFEC
Removal of various recreation facilities located on the banks of the existing reservoirs which could affect water supply or water rights.	2, 3, 5	NCFEC	None	NCFEC
Flow changes downstream from Iron Gate Dam could affect water supply downstream from Seiad Valley.	2, 3, 5	LTS (long term)	None	LTS (long term)
Changes in flow downstream from Iron Gate Dam could affect water rights holders.	2, 3, 5	LTS (long term)	None	LTS (long term)
Sediment release during reservoir drawdown could affect Klamath River geomorphology and water intake pumps downstream from Iron Gate Dam.	2, 3, 5	S (short term)	WRWS-1: Modifications to Intake Points	LTS (short term)
Keno Transfer				
Implementation of the Keno Transfer could cause changes to operations affecting water levels upstream of Keno Dam, which could cause changes to water supply or water rights.	2, 3	NCFEC	None	NCFEC
East and Westside Facilities – Programmatic Measure				

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Decommissioning of the East and Westside Facilities and redirecting of water flows could affect water users reliant on a diversion from the West Canal.	2, 3	NCFEC	None	NCFEC
<i>City of Yreka Water Supply Pipeline Relocation – Programmatic Measure</i>				
Removal of Iron Gate Dam would require relocation of the Yreka Water Supply Pipeline which could affect water supply.	2, 3, 5	NCFEC	None	NCFEC
<i>KBRA – Programmatic Measures</i>				
Implementation of the trap and haul element of the Fisheries Reintroduction and Management would require water rights to divert water for the fish handling facilities.	2, 3	LTS (long term)	None	LTS (long term)
Implementation of Wood River Wetland Restoration by the Bureau of Land Management would result in changes to storage opportunities at Agency Lake, which could affect water supply.	2, 3	LTS (long term)	None	LTS (long term)
Implementation of Water Diversion Limitations to Reclamation’s Klamath Project could result in changes to water diversions, which may affect water rights and water supply.	2, 3	LTS (long term)	None	LTS (long term)
Implementation of the On-Project Plan to allow for full implementation of Water Diversion Limitations to Reclamation’s Klamath Project would result in changes to water diversions for irrigation in dry years, which could affect water rights or adjudicated rights.	2, 3	B (long term)	None	B (long term)
The study of additional off-stream storage opportunities in the Upper Klamath Basin to identify new storage opportunities, could affect water supply.	2, 3	NCFEC	None	NCFEC
Implementation of the Water Use Retirement Program increases instream flow to Upper Klamath Lake which could affect water rights upstream of Upper Klamath Lake.	2, 3	LTS (long term)	None	LTS (long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Implementation of the Water Use Retirement Program increases instream flow to Upper Klamath Lake which could affect water supply upstream of Upper Klamath Lake.	2, 3	NCFEC	None	NCFEC
Implementation of Off-Project Water Settlement negotiations could affect water rights and adjudicated rights upstream of Upper Klamath Lake.	2, 3	B (long term) resolved water rights	None	B (long term) resolved water rights
	2, 3	LTS (long term) unresolved water rights	None	LTS (long term) unresolved water rights
Implementation of Off-Project Reliance Program could change water deliveries for irrigation downstream from Upper Klamath Lake to Off-Project water users affecting water rights.	2, 3	LTS (long term)	None	LTS (long term)
Implementation of an Emergency Response Plan could result in a change to water supply deliveries in the event of failure to a Klamath Reclamation Project facility or dike on Upper Klamath Lake or Lake Ewauna.	2, 3	B (long term)	None	B (long term)
Implementation of Climate Change Assessment and Adaptive Management could result in changes to water deliveries depending on climatic changes.	2, 3	B (long term)	None	B (long term)
Implementation of Interim Flow and Lake Program during the interim period could change water deliveries affecting water supply.	2, 3	LTS (long term)	None	LTS (long term)
Implementation of Drought Plan water and resource management actions could result in changes to water supply deliveries for Klamath Basin interests during drought years.	2, 3	B (long term)	None	B (long term)
<i>Trap and Haul – Programmatic Measure</i>				
Implementation of the trap and haul measures could require water rights to divert water for the fish handling facilities.	4, 5	LTS (long term)	None	LTS (long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
3.9 Air Quality				
Vehicle exhaust and fugitive dust emissions from dam removal activities and construction of fish passage could increase emissions of VOC, NO _x , CO, SO ₂ , PM ₁₀ , and PM _{2.5} to levels that could exceed Siskiyou County's thresholds of significance.	1	Not quantified ^b	None	None
	2, 3, 5	S (short term)	AQ-1: MY 2015 or newer engines for offroad construction equipment AQ-2: MY 2000 or newer engines for on-road construction equipment AQ-3: MY 2010 or newer engines for haul trucks AQ-4: Dust control measures during blasting operations	S (short term)
	4	LTS (short term)	None	LTS (short term)
Reservoir restoration actions could result in short-term and temporary increases in criteria pollutant emissions from the use of helicopters, trucks, and barges that could exceed Siskiyou County's thresholds of significance.	2, 3, 5	LTS (short term)	None	LTS (short term)
Relocation and demolition of various recreation facilities could result in short-term and temporary increases in criteria pollutant emissions from the operation of construction equipment that could exceed Siskiyou County's thresholds of significance.	2, 3, 5	LTS (short term)	None	LTS (short term)
Vehicle exhaust and fugitive dust emissions from demolition activities exceed the de minimus thresholds in 40 CFR 93.153 that would require the development of a general conformity determination.	2, 3, 4, 5	General Conformity Determination not required	None	None
Fugitive dust emissions from demolition activities could impair visibility in Federal Class I areas.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Activities associated with interim measure (IM) 7 J.C. Boyle Gravel Placement and/or Habitat Enhancement, could result in short-term and temporary increases in criteria pollutants from vehicle exhaust and fugitive dust that could exceed Siskiyou County's thresholds of significance.	1,2,3	LTS (short term)	None	LTS (short term)
Activities associated with interim measure (IM) 8 J.C. Boyle Bypass Barrier Removal could result in short-term and temporary increases in criteria pollutants from vehicle exhaust and fugitive dust that could exceed Siskiyou County's thresholds of significance.	1	LTS (short term)	None	LTS (short term)
Activities associated with interim measure (IM) 16 Water Diversions could result in short-term and temporary increases in criteria pollutants from vehicle exhaust and fugitive dust that could exceed Siskiyou County's thresholds of significance.	2,3	LTS (short term)	None	LTS (short term)
<i>Keno Transfer</i>				
Implementation of the Keno Transfer could have adverse effects on air quality.	2, 3	NCFEC	None	NCFEC
<i>East and Westside Facilities – Programmatic Measure</i>				
Decommissioning the East and Westside Facilities could cause adverse air quality effects.	2, 3	LTS (long term)	None	LTS (long term)
<i>City of Yreka Water Supply Pipeline Relocation – Programmatic Measure</i>				
Relocation of the City of Yreka Water Supply Pipeline could result in short-term and temporary increases in criteria pollutant emissions from vehicle exhaust and fugitive dust that could exceed Siskiyou County's thresholds of significance.	2, 3, 5	LTS (short term)	None	LTS (short term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
<i>KBRA – Programmatic Measures</i>				
Construction activities associated with the KBRA programs could result in temporary increases in air quality pollutant emissions from vehicle exhaust and fugitive dust.	2, 3	S (short term)	AQ-1: Model Year 2015 or newer engines for Off-Road Construction Equipment AQ-2: Model Year 2000 or newer engines for On-Road Construction Equipment AQ:3 Model Year 2010 or newer engines for On-Road Heavy Duty Vehicles	S ⁹ (short term)
Operational activities associated with the Fisheries Reintroduction and Management Plan could result in temporary increases in air quality pollutant emissions from vehicle exhaust associated with trap and haul activities.	2, 3	S (short term)	AQ-1: Model Year 2015 or newer engines for Off-Road Construction Equipment AQ-2: Model Year 2000 or newer engines for On-Road Construction Equipment AQ:3 Model Year 2010 or newer engines for On-Road Heavy Duty Vehicles	S ⁹ (short term)
<i>Trap and Haul Operations – Programmatic Measure</i>				
Implementation of trap and haul measures could result in temporary increases in air quality pollutant emissions from vehicle exhaust.	4, 5	S (short term)	AQ-1: Model Year 2015 or newer engines for Off-Road Construction Equipment AQ-2: Model Year 2000 or newer engines for On-Road Construction Equipment AQ:3 Model Year 2010 or newer engines for On-Road Heavy Duty Vehicles	LTS (short term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
3.10 Greenhouse Gases/Global Climate Change				
Vehicle exhaust from dam removal activities and construction of fish passage could increase GHG emissions in the short term to levels that could exceed the designated significance criteria.	1	NCFEC	None	NCFEC
	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
Reservoir restoration actions could result in short-term increases in GHG emissions from the use of helicopters, trucks, and barges.	1, 2, 3, 5	LTS (short term)	None	LTS (short term)
Removing or reducing a renewable source of power by removing the dams or developing fish passage could result in increased GHG emissions from possible non-renewable alternate sources of power.	1	NCFEC	None	NCFEC
	2, 3, 4, 5	S (long term)	CC-1 - Market Mechanisms CC-2 - Energy Audit Program CC-3 - Energy Conservation Plan	S (long term)
The demolition of various recreation facilities which could result in short-term increases in GHG emissions from vehicle exhaust.	2, 3, 5	LTS (short term)	None	LTS (short-term)
Activities associated with interim measures (IM) 7 J.C. Boyle Gravel Placement and/or Habitat Enhancement could result in short-term and temporary increases in GHG emissions from vehicle exhaust.	1,2,3	LTS (short term)	None	LTS (short term)
Activities associated with interim measures (IM) 8 J.C. Boyle Bypass Barrier Removal could result in short-term and temporary increases in GHG emissions from vehicle exhaust.	1	LTS (short term)	None	LTS (short term)
Activities associated with interim measures (IM) 16 Water Divisions could result in short-term and temporary increases in GHG emissions from vehicle exhaust.	2,3	LTS (short term)	None	LTS (short term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
<i>Trap and Haul Operations – Programmatic Measure</i>				
Implementation of trap and haul measures could result in temporary increases in GHG emissions from vehicle exhaust	4,5	LTS (short term)	None	LTS (short term)
<i>Keno Transfer</i>				
Implementation of the Keno Transfer could have adverse effects on greenhouse gases and climate change.	2, 3	NCFEC	None	NCFEC
<i>East and Westside Facilities – Programmatic Measure</i>				
Decommissioning the East and Westside Facilities could cause adverse greenhouse gas and climate change effects.	2, 3	LTS (long term)	None	LTS (long term)
<i>City of Yreka Water Supply Pipeline Relocation – Programmatic Measure</i>				
Relocation of the City of Yreka Water Supply Pipeline could result in short-term increases in GHG emissions from vehicle exhaust.	2, 3, 5	LTS (short term)	None	LTS (short term)
<i>KBRA – Programmatic Measures</i>				
Construction activities associated with the KBRA programs involving construction could cause temporary increases in GHG emissions and climate change.	2, 3	LTS (short term)	None	LTS (short term)
Operational activities associated with the Fisheries Reintroduction and Management Plan could result in temporary increases in GHG emissions from vehicle exhaust associated with trap and haul activities.	2, 3	LTS (short term)	None	LTS (short term)
Implementation of the Power for Water Management Program of the KBRA could create new renewable energy sources which would provide affordable electricity to allow efficient use, distribution, and management of water.	2, 3	B (long term)	None	B (long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Implementation of the Drought Plan and the Climate Change Assessment and Adaptive Management Plan could affect climate change-related impacts.	2, 3	B (long term)	None	B (long term)
3.11 Geology, Soils, and Geologic Hazards				
Continued impoundment of water in the reservoirs could continue to trap sediment at rates similar to historical rates.	1, 4	NCFEC	None	NCFEC
Continued impoundment of water in the reservoirs could continue to prevent access to the diatomite beds at Copco 1 Reservoir.	1, 4	NCFEC	None	NCFEC
Draining of the reservoirs could uncover diatomite beds at Copco 1 Reservoir; however the land would be transferred to a State agency which would not allow commercial use, access to the mineral resource would not be changed.	2, 3, 5	NCFEC	None	NCFEC
Construction and deconstruction activities could change erosion patterns through heavy vehicle use, excavation, and grading which could result in soil erosion.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
Draining of the reservoirs could cause instability along the banks of the reservoirs.	2, 3, 5	LTS (short term)	None	LTS (short term)
Draining of Copco 1 Reservoir could eliminate wave induced erosion thereby improving stability for upland hillsides and reducing the potential for erosion.	2, 3, 5	LTS (long term)	None	LTS (long term)
Draining of the reservoirs could cause river bank erosion downstream.	2, 3, 5	LTS (short term)	None	LTS (short term)
Draining of the reservoirs could result in short-term increases in sedimentation in slow-moving eddies and pools downstream from the reservoirs to the Klamath River estuary.	2, 3, 5	LTS (short term)	None	LTS (short term)
Draining of the reservoirs could result in changes to seismic or volcanic activity.	2, 3, 5	LTS (short term)	None	LTS (short term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Draining of the reservoirs could result in long-term changes in the amount of erosion of the exposed reservoir bottom sediment remaining in the river channel.	2, 3, 5	LTS (long term)	None	LTS (long term)
Draining of the reservoirs could result in long-term changes to downstream sediment deposition from the erosion of remaining reservoir sediments.	2, 3, 5	LTS (long term)	None	LTS (long term)
Draining of the reservoirs could leave sediments that would dry out and could affect restoration activities and/or future road construction activities.	2, 3, 5	S (long term)	GEO-1: Geotechnical Analysis	LTS (long term)
Dam removal activities would include the removal of various recreation facilities which could affect geology and soils.	2, 3, 5	NCFEC	None	NCFEC
<i>Keno Transfer</i>				
The Keno Transfer could have adverse effects to geology, soils, or geologic hazards.	2, 3	NCFEC	None	NCFEC
<i>East and Westside Facilities – Programmatic Measure</i>				
The decommissioning of the East and Westside Facilities could have adverse effects to geology, soils, or geologic hazards.	2, 3	NCFEC	None	NCFEC
<i>City of Yreka Water Supply Pipeline Relocation – Programmatic Measure</i>				
Removal of Iron Gate Dam would require relocation of the Yreka Water Supply Pipeline which could affect geology and soils.	2, 3,5	NCFEC	None	NCFEC
<i>KBRA – Programmatic Measures</i>				
Implementation of the Phase I Fisheries Restoration Plan could result in construction related sediment erosion.	2, 3	LTS (short term) B (long term)	None	LTS (short term) B (long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
3.13 Cultural and Historic Resources				
Under the No Action/No Project Alternative current effects/impacts on historic properties/ historical resources, other cultural resources, and human remains will continue to occur.	1, 4	NCFEC	None	NCFEC
Dam removal and construction of fish passage facilities could result in direct effects/impacts to J.C. Boyle Dam, Copco 1 Dam, Copco 2 Dam, and Iron Gate Dam, their associated hydroelectric facilities, and on the KHHD, which is considered eligible for inclusion on the National Register and California Register.	2, 3, 4, 5	S (long term)	CHR-1: Update the Klamath Hydroelectric Project Request for Determination CHR-2: MOU Under Section 106 and Preparation of Monitoring and Cultural Resources Management Plan CHR-3: Respect and Maintain Confidentiality of Sensitive Information CHR-4:Treatment of Indian Human Remains	S (long term)
Reservoir drawdown associated with dam removal could affect/impact archaeological and historic sites, TCPs, and cultural landscapes that are eligible for inclusion on the National Register and/or California Register and possibly Indian human remains.	2, 3, 5	S (long term)	CHR-1: Update the Klamath Hydroelectric Project Request for Determination CHR-2: MOU Under Section 106 and Preparation of Monitoring and Cultural Resources Management Plan CHR-3: Respect and Maintain Confidentiality of Sensitive Information CHR-4:Treatment of Indian Human Remains	LTS (long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Construction activities including use of haul roads and disposal sites for demolition debris could affect/impact archaeological and historic sites, TCPs, and cultural landscapes that are eligible for inclusion on the National Register or California Register.	2, 3, 4, 5	S (short term)	CHR-1: Update the Klamath Hydroelectric Project Request for Determination CHR-2: MOU Under Section 106 and Preparation of Monitoring and Cultural Resources Management Plan CHR-3: Respect and Maintain Confidentiality of Sensitive Information CHR-4: Treatment of Indian Human Remains	LTS (short term)
Removal of the recreational facilities after reservoir drawdown may affect archaeological or historic sites that could be eligible for inclusion on the National Register or California Register or human remains.	2, 3	S (long term)	CHR-1: Update the Klamath Hydroelectric Project Request for Determination CHR-2: MOU Under Section 106 and Preparation of Monitoring and Cultural Resources Management Plan CHR-3: Respect and Maintain Confidentiality of Sensitive Information CHR-4: Treatment of Indian Human Remains	LTS (long term)
<i>Keno Transfer</i>				
The Transfer of Keno Dam to the DOI could have adverse effects to historic properties or historic resources.	2, 3	B (long term)	None	B (long term)
<i>East and Westside Facilities – Programmatic Measure</i>				
The decommissioning of the East and Westside Facilities could have adverse effects on historic resources or historic properties.	2, 3	LTS (long term)	None	LTS (long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
<i>City of Yreka Water Supply Pipeline Relocation – Programmatic Measure</i>				
Installation of the Yreka Water Supply Pipeline could affect/impact archaeological and historic sites that are eligible for inclusion on the National Register or California Register.	2, 3	S (long term)	CHR-1: Update the Klamath Hydroelectric Project Request for Determination CHR-2: MOU Under Section 106 and Preparation of Monitoring and Cultural Resources Management Plan CHR-3: Respect and Maintain Confidentiality of Sensitive Information CHR-4:Treatment of Indian Human Remains	LTS (long term)
<i>KBRA – Programmatic Measures</i>				
Implementation of the KBRA programs including the Phase 1 and 2 Fisheries Restoration Plans, Fisheries Reintroduction and Management Plan, Wood River Wetland Restoration Project, On-Project Plan, Water Use Retirement Program, Fish Entrainment Reduction, Klamath Tribes Interim Fishing Site, and Mazama Forest Project could result in impacts/effects to archaeological and historic sites, TCPs, and cultural landscapes that are eligible for inclusion on the National Register and/or California Register and possibly Indian human remains.	2, 3	S (long term)	CHR-1: Update the Klamath Hydroelectric Project Request for Determination CHR-2: MOU Under Section 106 and Preparation of Monitoring and Cultural Resources Management Plan CHR-3: Respect and Maintain Confidentiality of Sensitive Information CHR-4:Treatment of Indian Human Remains	S ¹⁰ (long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Establishment of the Klamath Tribes Interim Fishing Site and implementation of the Mazama Forest Project could result in impacts/effects to archaeological and historic sites, TCPs, and cultural landscapes that are eligible for inclusion on the National Register and/or California Register and possibly Indian human remains.	2, 3	S (long term)	CHR-1: Update the Klamath Hydroelectric Project Request for Determination CHR-2: MOU Under Section 106 and Preparation of Monitoring and Cultural Resources Management Plan CHR-3: Respect and Maintain Confidentiality of Sensitive Information CHR-4: Treatment of Indian Human Remains	LTS (long term)
Implementation of the Mazama Forest Project could result in impacts/effects to archaeological and historic sites, TCPs, and cultural landscapes that are eligible for inclusion on the National Register and possibly Indian human remains.	2, 3	S (long term)	CHR-1: Update the Klamath Hydroelectric Project Request for Determination CHR-2: MOU Under Section 106 and Preparation of Monitoring and Cultural Resources Management Plan CHR-3: Respect and Maintain Confidentiality of Sensitive Information CHR-4: Treatment of Indian Human Remains	LTS (long term)
3.14 Land Use, Agricultural and Forest Resources				
The continued operation of and impoundment of water at the Four Facilities could conflict with applicable land use plans, policies, or regulations adopted for the purpose of avoiding or mitigating an environmental effect.	1	NCFEC	None	NCFEC

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
The exposure of the currently inundated lands from the removal of the Four Facilities could conflict with applicable land use plans, policies, or regulations adopted for the purpose of avoiding or mitigating an environmental effect.	2, 3	NCFEC	None	NCFEC
The construction of fish passage infrastructure at the Four Facilities, or the construction activities associated with the removal of Copco 1 and Iron Gate dams and the construction of fish passage infrastructure at J.C. Boyle and Copco 2 could conflict with applicable land use plans, policies, or regulations adopted for the purpose of mitigating an environmental effect.	4, 5	NCFEC	None	NCFEC
Both the continued impoundment of water at the Four Facilities and dam removal could result in the direct conversion of farmland to non-agricultural use or conflict with the Williamson Act or agricultural zoning in the Upper Klamath Basin.	1, 2, 3, 4, 5	NCFEC	None	NCFEC
Both the continued impoundment of water at the Four Facilities and dam removal could result in the direct conversion of forest lands to non-forest use or conflict with forest zoning.	1, 2, 4, 3, 5	NCFEC	None	NCFEC
Continued impoundment of water at the Four Facilities could indirectly convert farmland to non-agricultural use or forest land to non-forest use.	1, 4	NCFEC	None	NCFEC
Ongoing restoration actions could affect land use, agriculture, and forest resources.	1, 4	NCFEC	None	NCFEC
Construction activities including the creation of temporary roads, staging areas and construction sites during dam removal could result in the conversion of farmland to non-agricultural use or conversion of forest land to non-forest use.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
The construction of fish passage infrastructure at the Four Facilities, or the construction activities associated with the removal of Copco 1 and Iron Gate dams and the construction of fish passage infrastructure at J.C. Boyle and Copco 2, could result in the indirect conversion of farmland to non-agricultural use or conflict with the Williamson Act or agricultural zoning in the Upper Klamath Basin due to uncertain water supplies.	4, 5	NCFEC	None	NCFEC
Construction activities associated with dam removal could require new, permanent roads to be constructed to provide access to new recreation areas, which could constitute a change in the existing environment.	2, 3, 5	LTS (short term)	None	LTS (short term)
Removal of recreational facilities currently located on the banks of the existing reservoirs could change land use classification.	2, 3	NCFEC	None	NCFEC
The construction and development of fish passage facilities would require new permanent roads to be created to provide access to the Klamath Hydroelectric Project facilities which could change land use and create conflicts with applicable plans and policies or otherwise cause a significant land use impact due to existing zoning and land uses.	4, 5	LTS (short term)	None	LTS (short term)
<i>Keno Transfer</i>				
The transfer of ownership of Keno Dam from PacifiCorp to Reclamation could result in a change in land use.	2, 3	NCFEC	None	NCFEC
<i>East and Westside Facilities – Programmatic Measure</i>				
The decommissioning of the East and Westside Facilities could impact land use.	2, 3	NCFEC	None	NCFEC

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
<i>City of Yreka Water Supply Pipeline Relocation – Programmatic Measure</i>				
Dam removal would require the relocation of the Yreka water supply line and could result in a change in the existing environment and surrounding environment.	2, 3, 5	NCFEC	None	NCFEC
<i>KBRA – Programmatic Measures</i>				
The Fisheries Reintroduction and Management Plan and the construction of fish handling facilities for trap and haul operations could conflict with applicable land use plans, policies, or regulations adopted for the purpose of avoiding or mitigating an environmental effect.	2,3	LTS (long term)	None	LTS (long term)
The implementation of the Water Diversion Limitation Program could convert farmland to non-agricultural uses.	2,3	LTS (long term)	None	LTS (long term)
The Water Use Retirement Program could result in the fallowing or conversion of agricultural land to non-agricultural uses, such as open space or wetland restoration areas	2,3	B	None	B
The Power for Water Management Program could affect land use in the Klamath Hydroelectric Project area.	2,3	LTS (long term)	None	LTS (long term)
The KBRA's Mazama Forest Project could result in the conversion of forest land to non-forest use or conflict with forest zoning.	2,3	NCFEC	None	NCFEC
<i>Trap and Haul – Programmatic Measure</i>				
Construction of fish handling facilities for trap and haul operations could change land use.	4, 5	LTS (long term)	None	LTS (long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
3.17 Population and Housing				
Construction activities could employ non-local workers, who would need housing for the duration of their employment.	1	NCFEC	None	NCFEC
	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
Construction, restoration, and monitoring activities associated with new programs could create new jobs and could employ non-local workers, who would need housing for the duration of their employment.	1	LTS (short term)	None	LTS (short term)
Removal of recreation facilities and related construction activities could result in an increase in construction workers requiring housing.	2, 3, 5	NCFEC	None	NCFEC
<i>Keno Transfer</i>				
The transfer of ownership of Keno Dam from PacifiCorp to Reclamation could affect population and housing.	2, 3	NCFEC	None	NCFEC
<i>East and Westside Facilities – Programmatic Measure</i>				
The decommissioning of the East and Westside Facilities could impact population and housing.	2, 3	NCFEC	None	NCFEC
<i>City of Yreka Water Supply Pipeline Relocation – Programmatic Measure</i>				
Dam removal would require relocation of the Yreka Water Supply Pipeline and could result in an increase in construction workers requiring housing.	2, 3, 5	NCFEC	None	NCFEC
<i>KBRA – Programmatic Measures</i>				
Construction and monitoring activities associated with the KBRA programs could employ non-local workers who would need housing for the duration of their employment.	2,3	LTS (short term)	None	LTS (short term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
3.18 Public Health and Safety, Utilities and Public Services, Solid Waste, Power				
Continued impoundment of water at the reservoirs under annual license renewals would allow hydropower generation to continue subject to the conditions of the Reclamation Biological Opinions, which would have the potential to decrease hydropower production.	1	NCFEC	None	NCFEC
Construction activities related to the ongoing restoration and management activities could impact public health and safety.	1	NCFEC	None	NCFEC
Construction activities from dam removal and fish passage facilities could result in public health and safety risks.	2, 3, 4, 5	S (short term)	PHS-1: Public Safety Management Plan	LTS (short term)
Construction activities could increase public hazards by placing construction equipment in waterways, roadways, and other areas accessible by residents, recreational visitors, and potential spectators of the deconstruction activities.	2, 3, 4, 5	S (short term)	PHS-1: Public Safety Management Plan PHS-2: Fire Management Plan	LTS (short term)
Construction activities could increase the risk of wildfires.	2, 3, 4, 5	S (short term)	PHS-2: Fire Management Plan	LTS (short term)
Dam removal could eliminate a water source for wildfire services and could increase response times.	2, 3, 5	LTS (long term)	None	LTS (long term)
Dam removal would eliminate a water source for residential firefighting in and around Copco Village, and could increase the risk to homes from fire.	2, 3, 5	LTS (long term)	None	LTS (long term)
Construction activities could affect police services by temporarily increasing the population of construction workers, lengthening response times due to construction traffic on area roads, and exposing construction areas to theft and/or vandalism.	2, 3, 4, 5	NCFEC	None	NCFEC
Construction activities could require the use of electricity and natural gas supplies in the study area.	2, 3, 4, 5	NCFEC	None	NCFEC

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
The removal of recreational facilities currently located on the banks of the existing reservoirs could affect public health and safety.	2, 3, 5	S (long term)	PS-1: Public Safety Management Plan PHS-2: Fire Management Plan	LTS (long term)
Construction activities could affect public services and utilities in the counties and cities in the study area.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
Construction activities could result in the need for new temporary access roads.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
Construction activities (including Signage and Construction Traffic Management BMP) could affect road conditions by increasing traffic from heavy construction vehicles which could affect public health and safety.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
Construction activities could generate a substantial amount of solid waste which could affect public services and utilities.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
Dam removal would remove existing hydropower facilities, resulting in a loss of hydropower generation which could affect the supply of electricity.	2, 3, 5	LTS (long term)	None	LTS (long term)
Development of fish passage would reduce power generation at the existing hydropower facilities due to bypass stream flow requirements which could affect the supply of electricity.	4, 5	LTS (long term)	None	LTS (long term)
Dam removal could increase available mosquito habitat and could increase the risk of disease transmission in the short term.	2, 3, 5	LTS (short term)	None	LTS (short term)
Leaving dam facilities and infrastructure in place could have the potential to result in public health and safety risks.	4	NCFEC	None	NCFEC
	3, 5	LTS (long term)	None	LTS (long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
<i>Keno Transfer</i>				
Under the Proposed Action, the Keno Facility will be transferred to the DOI, which could cause adverse effects to Public Health and Safety.	2, 3	NCFEC	None	NCFEC
<i>East and Westside Facilities – Programmatic Measure</i>				
Under the Proposed Action, the East and Westside Facilities will be decommissioned, resulting in the loss of generated power.	2, 3	LTS (long term)	None	LTS (long term)
<i>City of Yreka Water Supply Pipeline Relocation – Programmatic Measure</i>				
Construction activities could affect the City of Yreka’s municipal water supply by damaging or exposing the Yreka Water Supply Pipeline prior to its relocation.	2, 3, 5	LTS (short term)	None	LTS (short term)
The proposed above-ground location of the Yreka Water Supply Pipeline could increase the risk of vandalism to the pipeline.	2, 3, 5	LTS (long term)	None	LTS (long term)
<i>KBRA – Programmatic Measures</i>				
Prescribed burning and mechanical thinning under the Phase I and II Fisheries Restoration Plans could affect Public Services and Utilities.	2, 3	S (short term); B (long term)	PHS-2: Fire Management Plan	LTS (short term); B (long term)
Construction activities associated with the KBRA programs could result in public health and safety impacts.	2, 3	B (long term)	None	B (long term)
Implementation of the Power for Water Management Program could create new renewable energy sources.	2, 3	B (long term)	None	B (long term)
Completing the Emergency Response Plan could have beneficial effects on Public Services and Public Safety.	2, 3	B (long term)	None	B (long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
3.19 Scenic Quality				
Continued impoundment of water at the Four Facilities could result in water quality impacts that could have long-term impacts on scenic quality.	1, 4	NCFEC	None	NCFEC
Continued existence of the buildings and other man-made structures could have the impact that they would remain inconsistent with the VRM classification of the surrounding area (where such inconsistency is defined as a criterion of significance).	1, 3, 4, 5	NCFEC	None	NCFEC
Ongoing fish habitat restoration actions could result in short-term and long-term impacts on scenic resources.	1	S (short term from construction); B (long term)	None	S (short term from construction); B (long term)
Dam removal could result in impacts on scenic resources from removal of dams and facilities.	2, 3, 5	B (long term)	None	B (long term)
The removal of historic properties could result in short-term and long-term impacts on scenic resources.	2, 3, 5	S (short term and long term)	None	S (long term)
Dam removal could result in short-term and long-term impacts on scenic resources in formerly inundated reservoir areas.	2, 3, 5	S (short term and long term)	None	S (short term and long term)
Deconstruction and restoration activities could result in short-term impacts on scenic resources in the immediate vicinity of the Four Facilities.	2, 3, 5	S (short term); B (long term)	None	S (short term); B (long term)
Replacement of the existing wooden Lakeview Bridge just downstream from Iron Gate Dam with a concrete bridge could result in short-term and long-term impacts on scenic resources.	2, 3	S (short term); LTS (long term)	None	S (short term); LTS (long term)
Demolition of existing recreation facilities, such as campgrounds and boat ramps, from the reservoir banks to the new river shoreline would result in short-term and long-term impacts on scenic resources.	2, 3	S (short term); LTS (long term)	None	S (short term); LTS (long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Deconstruction activities could create a new source of light or glare that could adversely affect nighttime views in the area.	2, 3, 4, 5	S (short term)	SQ-1: Measures to Reduce Nighttime Light and Glare	LTS (short term)
Sediment release during dam and reservoir removal could cause temporary changes in water quality and the appearance of the Klamath River in the area of the dams and downstream from Iron Gate Dam.	2, 3, 5	S (short term)	None	S (short term)
Removal of the dams and facilities could result in long-term impacts on scenic resources from changes to water quality.	2, 3, 5	B (long term)	None	B (long term)
Demolition, construction, and restoration activities for the fishways could cause short-term adverse effects on the scenic vistas in the immediate vicinity of the Four Facilities.	4, 5	S (short term)	None	S (short term)
Construction of fishways could cause changes in the appearance of the Klamath River in the area of the dams and downstream from Iron Gate Dam.	4, 5	LTS (short term)	None	LTS (short term)
Fishways could cause substantial long-term impacts on scenic resources.	4, 5	S (long term)	SQ-1: Measures to Minimize Scenery Disturbances	S (long term)
<i>Keno Transfer</i>				
Implementation of the Keno Transfer could affect scenic resources.	2, 3	NCFEC	None	NCFEC
<i>East and Westside Facilities – Programmatic Measure</i>				
Decommissioning of the East and Westside canals and hydropower facilities could affect scenic resources.	2, 3	LTS (long term)	None	LTS (long term)
<i>City of Yreka Water Supply Pipeline Relocation – Programmatic Measures</i>				
Construction of a new, elevated City of Yreka Water Supply Pipeline and steel pipeline bridge to support the pipe above the river could result in short-term and long-term impacts on scenic resources.	2, 3, 5	S (short term and long term)	SQ-2: Measures to Minimize Scenery Disturbances	S (short term and long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
<i>KBRA – Programmatic Measures</i>				
Construction activities associated with the Fisheries Restoration Plan- Phase I and Phase II could result in impacts on scenic resources.	2, 3	LTS (short term)	None	LTS (short term)
The Fisheries Restoration Plan- Phase I and Phase II could result in long-term impacts on scenic resources.	2, 3	B (long term)	None	B (long term)
The Wood River Wetland Restoration Project could result in long-term impacts on scenic resources.	2, 3	LTS (long term)	None	LTS (long term)
Construction activities associated with the WURP could result in impacts on scenic resources.	2, 3	LTS (short term)	None	LTS (short term)
The Water Diversion Limitations, On-Project Plan, WURP, and Interim Flow and Lake Level Programs could result in long-term impacts on scenic resources.	2, 3	LTS (short term)	None	LTS (short term)
Fish Entrainment Reduction could result in short-term and long-term impacts on scenic resources.	2, 3	LTS (short term and long term)	None	LTS (short term and long term)
Construction activities associated with the Klamath Tribes Interim Fish Site could result in impacts on scenic resources.	2, 3	LTS (short term)	None	LTS (short term)
The Klamath Tribes Interim Fish Site could result in long-term impacts on scenic resources.	2, 3	LTS (long term)	None	LTS (long term)
Construction of fish management structures would introduce new features into the landscape.	2, 3	S (long term)	SQ-2: Measures to Minimize Scenery Disturbances	S (long term)
<i>Trap and Haul – Programmatic Measure</i>				
Construction activities associated with fish collection facilities would introduce new features into the landscape.	4, 5	LTS (short term); S (long term)	SQ-2: Measures to Minimize Scenery Disturbances	LTS (short term); S (long term)
3.20 Recreation				
Continued existence of the reservoirs could change existing recreation access and opportunities.	1,4	NCFEC	None	NCFEC

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Construction activities associated with ongoing programs could temporarily restrict access to recreational opportunities.	1	LTS (short term)	None	LTS (short term)
Construction activities associated with ongoing programs could result in short-term water quality impacts that could affect recreational opportunities.	1	LTS (short term)	None	LTS (short term)
Ongoing actions correcting fish passage issues, reintroducing and monitoring fish species, and restoring aquatic habitat could increase recreational fishing and wildlife viewing opportunities in the basin.	1	B (long term)	None	B (long term)
Construction activities could temporarily restrict recreational access on and in the vicinity of the reservoirs.	1, 4	NCFEC	None	NCFEC
	2, 3, 5	LTS (short term)	None	LTS (short term)
Construction activities, such as demolition, would generate temporary impacts (i.e., increased noise and dust) and could decrease the quality of recreational experiences in the vicinity of the reservoirs.	2, 3, 5	LTS (short term)	None	LTS (short term)
Reservoir removal could permanently decrease the availability of reservoir/lake-based recreational opportunities.	1, 4	NCFEC	None	NCFEC
	2, 3, 5	LTS (long term)	None	LTS (long term)
Removal of recreation facilities could limit access to recreational opportunities along and within the newly formed river channel.	2, 3, 5	S (long term)	REC-1: Prepare a plan to develop new recreational facilities and river access points	LTS (long term)
Changes in flow and water quality following dam removal could impact developed recreational facilities upstream and downstream from the reservoirs.	2, 3, 5	LTS (long term)	None	LTS (long term)
Downstream sediment release during reservoir drawdown could decrease the quality of water-contact-based-recreation in the short term.	2, 3, 5	LTS (short term)	None	LTS (short term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Removal of impoundments and associated improvements in water quality and could impact water-contact-based recreational opportunities.	2, 3, 5	B (long term)	None	B (long term)
	1, 4	NCFEC	None	NCFEC
Changes to the floodplain or river channel and removal of recreation facilities as a result of dam removal could affect access to whitewater boating opportunities.	2, 3, 5	NCFEC - downstream from Iron Gate LTS - (short term) Hydroelectric Reach	None	NCFEC - downstream from Iron Gate LTS - (short term) Hydroelectric Reach
Changes in flows following dam removal could increase the number of days with acceptable flows for whitewater boating and recreational fishing activities in the Keno Reach and reaches downstream from Iron Gate Dam.	2, 3, 5	LTS (long term)	None	LTS (long term)
Changes in flows could increase the number of days with acceptable flows for whitewater boating and recreational fishing in the J.C. Boyle and Copco 2 Bypass Reaches.	2, 3, 5	B (long term)	None	B (long term)
Changes in flows could decrease the number of days with acceptable flows for whitewater boating and recreational fishing in the Hells Corner Reach.	1	NCFEC	None	NCFEC
	2, 3, 4, 5	S (long term) whitewater boating; LTS (long term) fishing	None	S (long term) whitewater boating; LTS (long term) fishing
Loss of peaking flows in the J.C. Boyle Peaking Reach could affect whitewater boating opportunities in the Hell's Corner Reach.	4, 5	S (long term)	None	S (long term)
Improved habitat for anadromous fish species following dam removal could affect recreational fishing opportunities in the long term.	2, 3, 4, 5	B (long term)	None	B (long term)
Implementation of Mitigation Measure REC-1 could permanently reduce recreational opportunities in the Klamath Basin.	2, 3, 5	LTS (long term)	None	LTS (long term)
<i>Keno Transfer</i>				
Transfer of the Keno Facility from PacifiCorp to DOI could affect recreational opportunities.	2, 3	NCFEC	None	NCFEC

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
<i>East and Westside Facilities – Programmatic Measure</i>				
The decommissioning of the East and Westside Facilities could have adverse effects on recreational resources.	2, 3	NCFEC	None	NCFEC
<i>City of Yreka Water Supply Pipeline Relocation – Programmatic Measure</i>				
The Yreka Water Supply Pipeline, currently under the Iron Gate Reservoir, would need to be relocated to avoid damage after the reservoir is removed, creating a change in existing recreational resources.	2, 3	NCFEC	None	NCFEC
<i>KBRA – Programmatic Measures</i>				
Construction activities associated with the KBRA could temporarily restrict recreational access.	2,3	LTS (short term)	None	LTS (short term)
Construction activities associated with KBRA programs could result in short-term water quality impacts which could affect recreational opportunities.	2,3	LTS (short term)	None	LTS (short term)
Fire treatment proposed in the Fisheries Restoration Plan could alter the visual setting and result in decreased recreational visitors to the Klamath Basin.	2,3	B (long term)	None	B (long term)
KBRA actions correcting fish passage issues, reintroducing and monitoring fish species, and restoring aquatic habitat could increase recreational fishing and wildlife viewing opportunities in the basin.	2,3	B (long term)	None	B (long term)
KBRA programs resulting in long-term water quality improvements could increase recreational opportunities throughout the Klamath Basin.	2,3	B (long term)	None	B (long term)
KBRA programs that enhance terrestrial wildlife and plant resources could increase recreational opportunities throughout the Klamath Basin.	2,3	B (long term)	None	B (long term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
3.21 Toxic/Hazardous Materials				
Continued operation of the Four Facilities could create a hazard to the public or the environment through the transport, use, or disposal of hazardous, toxic, or radiological waste (HTRW).	1, 4, 5	NCFEC	None	NCFEC
Construction activities could create a significant hazard to the public or the environment if they are located on a site which is included on a list of hazardous materials sites.	2, 3, 4, 5	NCFEC	None	NCFEC
Construction activities could create a hazard to the public or the environment through the transport, use, or disposal of HTRW.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
Construction activities could create a hazard to the public or the environment through the abatement and disposal of asbestos and lead-based paint.	2, 3, 5	LTS (short term)	None	LTS (short term)
Construction activities could create a hazard to the public or the environment through the accidental release of hazardous materials into the environment.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
Removal of various recreation facilities could create a hazard to the public or the environment through the accidental release of hazardous materials into the environment.	2, 3, 5	LTS (short term)	None	LTS (short term)
Keno Transfer				
The transfer of the Keno Facility to DOI could result in affects to HTRW.	2, 3	NCFEC	None	NCFEC
East and Westside Facilities – Programmatic Measure				
The decommissioning of the East and Westside Facilities could have adverse effects in terms of toxics and hazards.	2, 3	LTS (short term)	None	LTS (short term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
City of Yreka Water Supply Pipeline Relocation – Programmatic Measure				
Construction activities required to relocate the Yreka Water Supply Pipeline could create a hazard to the public or the environment through the accidental release of hazardous materials into the environment.	2, 3, 5	LTS (short term)	None	LTS (short term)
KBRA – Programmatic Measures				
Construction activities associated with the KBRA programs could create a significant hazard to the public or the environment through the transport, use, or disposal of hazardous materials encountered during construction.	2,3	LTS (short term)	None	LTS (short term)
Construction activities associated with the KBRA programs could create a significant hazard to the public or the environment through the accidental release of hazardous materials during construction activities.	2,3	LTS (short term)	None	LTS (short term)
3.22 Traffic and Transportation				
Traffic Flow Effects				
Changes in traffic volumes could affect traffic flow.	1	NCFEC	None	NCFEC
Construction activities associated with the continued implementation of ongoing restoration actions could cause temporary effects to traffic and transportation.	1	LTS ¹¹ (short term)	None	LTS (short term)
Construction vehicle trips could result in temporary traffic flow effects on I-5, OR66, US97, and access roads.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
Construction vehicle trips could result in temporary traffic flow effects on on-site roads.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
Construction vehicle trips during removal of recreation facilities associated with dam removal could result in temporary traffic flow effects on I-5, OR66, US97, and access roads.	2, 3, 5	LTS (short term)	None	LTS (short term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Implementation of the interim measures (IM's) 8 J.C. Boyle Bypass Barrier Removal and IM 16 Water Diversions could result in temporary traffic flow effects on I-5, OR66, US97, and access roads.	1 (IM 8)	LTS (short term)	None	LTS (short term)
	2 (IM 8 and 16)	LTS (short term)	None	LTS (short term)
Traffic Safety Effects				
Changes in traffic safety could occur.	1	NCFEC	None	NCFEC
Construction vehicle trips could cause traffic safety effects associated with the creation of dust along gravel roads.	2, 3, 5	LTS (short term)	None	LTS (short term)
Construction vehicle trips could cause traffic safety effects associated with vehicle turnouts along Copco Road, Topsy Grade/Ager-Beswick Road and OR66.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
Construction vehicle trips could cause traffic safety effects associated with sharp curves along Copco Road and OR66.	2, 3, 5	LTS (short term)	None	LTS (short term)
Removal of recreation facilities from the banks of the existing reservoirs down slope to the new river bed could result in traffic impacts along adjacent roadways.	2	LTS (short term)	None	LTS (short term)
Implementation of the interim measures (IM's) 7 J.C. Boyle Gravel Placement could cause traffic safety effects associated with sharp turns along Copco Road and OR66.	1,2,3	LTS (short term)	None	LTS (short term)
Implementation of the interim measures (IM's) 8 J.C. Boyle Bypass Barrier Removal could cause traffic safety effects associated with sharp turns along Copco Road and OR66.	1,2,3	LTS (short term)	None	LTS (short term)
Implementation of the interim measures (IM's) 16 Water Diversions could cause traffic safety effects associated with sharp turns along Copco Road and OR66.	2,3	LTS (short term)	None	LTS (short term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Road Condition Effects				
Changes in road conditions could occur.	1	NCFEC	None	NCFEC
Increased traffic volumes from heavy construction vehicles during construction activities could degrade road conditions and exceed bridge weight capacities. As part of the development of the construction plan, an in depth analysis of bridge and road capacity and state of repair will be conducted by the dam removal entity (DRE), with remedial actions taken prior to the commencement of facility deconstruction.	2, 3, 4, 5	S (short term)	TR-1: Relocate Jenny Creek Bridge and Culverts	LTS (short term)
Public Transit Effects				
Changes in public transit could occur.	1	NCFEC	None	NCFEC
Construction vehicle trip volumes and material hauling routes could affect regional transit service.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
Non-motorized Transportation Effects				
Changes in non-motorized transportation could occur.	1	NCFEC	None	NCFEC
The presence of construction vehicles along Copco and Topsy Grade/Ager-Beswick Roads could affect non-motorized transportation (i.e., bicyclists and pedestrians) due to high speeds and dust generation.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
Keno Transfer				
The transfer of the Keno Facility could impact traffic and transportation.	2, 3	NCFEC	None	NCFEC
East and Westside Facilities – Programmatic Measure				
Activities associated with the decommissioning of the East and Westside Facilities could affect traffic and transportation.	2, 3	LTS (short term)	None	LTS (short term)
City of Yreka Water Supply Pipeline Relocation – Programmatic Measure				
Construction vehicle trips during the relocation of the Yreka Water Supply Pipeline could result in temporary traffic flow effects on I-5, OR66, US97, and access roads.	2, 3, 5	LTS (short term)	None	LTS (short term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Construction vehicle trips during the relocation of the Yreka Water Supply Pipeline and removal of recreation facilities could cause traffic safety effects associated with sharp curves along Copco Road. The installation of signage at sharp corners would help to reduce this risk (See Appendix B).	2, 3, 5	LTS (short term)	None	LTS (short term)
<i>KBRA – Programmatic Measures</i>				
Activities associated with the KBRA actions that involve construction could cause temporary traffic effects.	2,3	LTS (short term)	None	LTS (short term)
Operational activities associated with the Fisheries Reintroduction and Management Plans could result in temporary traffic effects associated with trap-and-haul activities.	2, 3	LTS (short term)	None	LTS (short term)
<i>Trap and Haul Operations – Programmatic Measures</i>				
Traffic associated with the implementation of the prescriptions and trap and haul operations would cause traffic safety effects on OR66 and US97, access roads, and onsite roads.	4,5	LTS (short term)	None	LTS (short term)
3.23 Noise and Vibration				
Construction and deconstruction activities at the dam sites could cause a temporary increase in noise levels at Copco 1 Dam that could affect residents in the area.	1	NCFEC	None	NCFEC
	2, 3, 4, 5	S (short term)	NV-1: Noise and Vibration Control Plan	S (short term)
Construction and deconstruction activities at the dam sites could cause a temporary increase in nighttime noise levels at Iron Gate Dam.	1	NCFEC	None	NCFEC
	2, 3, 5	S (short term)	NV-1: Noise and Vibration Control Plan	S (short term)
	4	LTS (short term)	None	LTS (short term)
Reservoir restoration activities could result in short-term increases in noise levels in the project vicinity.	2, 3, 5	S (short term)	NV-1: Noise and Vibration Control Plan	S (short term)
Blasting activities at Copco 1 Dam could increase vibration levels.	2, 3, 5	S (short term)	NV-1: Noise and Vibration Control Plan	S (short term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
Construction activities at the dam sites could require the transport of waste to off-site landfills and construction worker commutes which would cause increases in noise along haul routes.	2, 3, 4, 5	LTS (short term)	None	LTS (short term)
Construction activities at the dam sites could increase short-term vibration levels.	2, 3, 5	S (short term)	NV-1: Noise and Vibration Control Plan	S (short term)
	4	LTS (short term)	None	LTS (short term)
<i>Keno Transfer</i>				
The transfer of Keno dam to the DOI could have adverse effects on noise and vibration.	2, 3	NCFEC	None	NCFEC
<i>East and Westside Facilities – Programmatic Measure</i>				
The decommissioning of the East and Westside Facilities could have adverse effects on Noise and Vibration.	2, 3	LTS (short term)	None	LTS (short term)
<i>KBRA – Programmatic Measures</i>				
Construction activities associated with the KBRA could cause temporary increases in noise and vibration levels.	2,3	S (short term)	NV-1: Noise and Vibration Control Plan	LTS (short term)
Operational activities associated with the Fisheries Reintroduction Management Plan could result in temporary increases in noise and vibration levels from vehicles associated with trap-and-haul activities.	2, 3	S (short term)	NV-1: Noise and Vibration Control Plan	LTS (short term)

Table 5-1. Summary of Environmental Impacts Relative to NEPA and CEQA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
<i>Trap and Haul – Programmatic Measure</i>				
Trap and Haul operations could result in temporary increases in noise and vibration levels from vehicles used to relocate fish.	4, 5	S (short term)	NV-1: Noise and Vibration Control Plan	LTS (short term)

¹ Short term is defined as <2 years.

² Long term is defined as 2-50 years.

³ Minimal short-term settling, sedimentation, or scouring is expected to occur in the Klamath River or the estuary as a result of dam removal (see Section 3.11.4.3), and estimates of baseline sediment delivery for the Klamath Basin indicate that long-term sediment delivery rates will not change substantially under dam removal (Stillwater Sciences 2010); therefore, there would be no indirect effect on water temperatures in the Klamath Estuary under Alternatives 2, 3, and 5.

⁴ Because these species were introduced and they occur in other nearby water bodies, their loss would not be considered significant from a biological perspective, and would benefit native species.

⁵ Periphyton are algae that grow attached to rocks and other substrates on a riverbed. Although sometime these species cause nuisance conditions, they are rarely considered toxic. Increased non-toxic periphyton biomass would not lead to increases in algal toxins in the Klamath River. Blooms of phytoplankton (suspended algae) occurring in the calm, lake-like waters are responsible for the production of algal toxins, such as microcystin, in the Klamath River downstream from Iron Gate Dam. Noxious phytoplankton would not thrive in the free flowing river following dam removal.

⁶ An editorial clarification was made to this determination for Alternative 5 in Section 3.4 Algae. As indicated by the analysis under the Proposed Action in Section 3.4, Algae, the determination for Alternative 5 in the Hydroelectric Reach from Copco 1 Reservoir to Iron Gate Reservoir should also have been a significant effect.

⁷ A nutrient reduction program in the Keno Impoundment/Lake Ewauna and Upper Klamath Lake would be designed to improve water quality (increasing seasonally low dissolved oxygen and reducing seasonal algal blooms) and fish passage through the Keno Impoundment/Lake Ewauna in summer and fall months, however implementation of this nutrient reduction program will require future environmental compliance investigations and a determination on significance cannot be made at this time.

⁸ Vehicle exhaust emissions associated with continued maintenance and operation of the Four Facilities are expected to be minimal and were not quantified for this analysis.

⁹ While Mitigation Measures AQ-1, 2, and 3 would be implemented to reduce impacts to LTS, emissions from any construction actions completed in the same year as hydroelectric facility removal actions may not be reduced to a less than significant level. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.

¹⁰ Studies will be conducted to identify cultural resources and reduce significant impacts to these resources. Implementation of specific plans and projects associated with the KBRA will require future environmental compliance as appropriate.

¹¹ While construction activities that would occur for the ongoing restoration programs are anticipated to result in potentially significant impacts to traffic and transportation, it is assumed that the use of best management practices incorporated into the project would minimize any traffic impacts to less than significant.

KEY:

Significance:

NCFEC = No Change From Existing Conditions

B = Beneficial

LTS = Less than Significant

S = Significant

N/A = Not Applicable

Alternatives:

1 = No Action/No Project

2 = Full Facilities Removal of Four Dams Alternative (Proposed Action)

3 = Partial Facilities Removal of Four Dams Alternative

4 = Fish Passage at Four Dams Alternative

5 = Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative

Table 5-2. Summary of Environmental Effects Relative to NEPA

Potential Impact	Alternative(s)	Effect Pursuant to NEPA	Mitigation
3.12 Tribal Trust			
<i>The Klamath Tribes</i>			
Continued operation of the four Klamath River dams would result in no change from existing conditions to the trust resources of The Klamath Tribes and other resources traditionally used by The Klamath Tribes.	1, 4	NCFEC	None
Removal of the Four Facilities and implementation of KBRA plans and programs, would address most of the water quality and aquatic resources issues related to The Klamath Tribes' trust resources and other resources traditionally used by the Tribes (see Sections 3.2, 3.3, and 3.5).	2, 3	B (long term)	None
	5 (at Copco and Iron Gate Reservoirs only)	B (long term)	None
Construction of fishways at the four dams would address a portion of the critical issues related to migratory fish that were identified by The Klamath Tribes; however the remaining critical issues affecting their trust resources and other resources traditionally used by the Klamath Tribes would persist.	4	B (long term)	None
<i>KBRA – Programmatic Measures</i>			
Implementation of the Tribal Fisheries and Conservation Management Program could result in impacts/effects to Trust Resources and other traditionally used resources.	2, 3	B (long term)	None
Establishment of The Klamath Tribes Interim Fishing Site could result in impacts/effects to Trust Resources and other traditionally used resources.	2, 3	B (long term)	None
Implementation of the Mazama Forest Project could result in impacts/effects to Trust Resources and other traditionally used resources.	2, 3	B (long term)	None
<i>Quartz Valley Community</i>			
Continued impoundment of water could affect traditionally used resources.	1, 4	NCFEC	None
Removal of the Four Facilities could affect traditionally used resources.	2, 3	B (long term)	None
	5 (at Copco and Iron Gate Reservoirs only)	B (long term)	None

Table 5-2. Summary of Environmental Effects Relative to NEPA

Potential Impact	Alternative(s)	Effect Pursuant to NEPA	Mitigation
<u>KBRA – Programmatic Measures</u>			
Implementation of the Tribal Fisheries and Conservation Management Program could result in impacts/effects to Trust Resources and other traditionally used resources.	2, 3	B (long term)	None
<i>Karuk</i>			
Continued operation of the four Klamath River dams would result in no change from existing conditions to traditionally use resources of the Karuk.	1, 4	NCFEC	None
Removal of the Four Facilities and implementation of KBRA plans and programs, would address most of the water quality and aquatic resources issues related to traditionally used resources of the Karuk (see Sections 3.2, 3.3, and 3.5).	2, 3	B (long term)	None
	5 (at Copco and Iron Gate Reservoirs only)	B (long term)	None
Construction of fishways at the four dams would address a portion of the critical issues related to migratory fish that were identified by the Karuk, however the remaining critical issues affecting their traditionally used resources.	4	B (long term)	None
<u>KBRA – Programmatic Measures</u>			
Implementation of the Tribal Fisheries and Conservation Management Program could result in impacts/effects to traditionally used resources.	2, 3	B (long term)	None
<i>Hoopa Valley Indian Tribe</i>			
Continued impoundment of water at the Four Facilities could affect tribal trust resources of the Hoopa Valley Indian Tribe and other resources traditionally used by the Hoopa Valley Indian Tribe.	1, 4	NCFEC	None
Removal of the Four Facilities and implementation of KBRA plans and programs, would address most of the water quality and aquatic resources issues related to the Hoopa Valley Indian Tribe trust resources and other traditionally used resources (see Sections 3.2, 3.3, and 3.5).	2, 3	B (long term)	None
	5 (at Copco and Iron Gate Reservoirs only)	B (long term)	None
Construction of fishways at the four dams would address a portion of the critical issues related to migratory fish that were identified by the Hoopa Valley Indian Tribe; however the remaining critical issues affecting their trust resources and other traditionally resources would persist.	4	B (long term)	None

Table 5-2. Summary of Environmental Effects Relative to NEPA

Potential Impact	Alternative(s)	Effect Pursuant to NEPA	Mitigation
<u>KBRA – Programmatic Measures</u>			
Implementation of the Tribal Fisheries and Conservation Management Program could result in impacts/effects to Trust Resources and other traditionally used resources.	2, 3	B (long term)	None
<u>Yurok Tribe</u>			
Continued impoundment of water at the Four Facilities would result in no change from existing conditions to the trust resources of the Yurok Tribe and other traditionally used resources.	1, 4	NCFEC	None
Removal of the Four Facilities and implementation of KBRA plans and programs, would address most of the water quality, terrestrial, and aquatic resources issues related to the Yurok Tribe trust resources and other traditionally used resources (see Sections 3.2, 3.3, and 3.5).	2, 3	B (long term)	None
	5 (at Copco and Iron Gate Reservoirs only)	B (long term)	B
Construction of fishways at the four dams would address a portion of the critical issues related to migratory fish that were identified by the Yurok Tribe; however the remaining critical issues affecting their trust resources and other resources traditionally used by the Yurok would persist (see Sections 3.2 and 3.3).	4	B (long term)	None
<u>KBRA – Programmatic Measures</u>			
Implementation of the Tribal Fisheries and Conservation Management Program could result in impacts/effects to Trust Resources and other traditionally used resources.	2, 3	B (long term)	None
<u>Resighini Rancheria</u>			
Continued impoundment of water at the Four Facilities would result in no change from existing conditions to Resighini Rancheria traditionally used resources.	1, 4	NCFEC	None
Removal of the Four Facilities and implementation of KBRA plans and programs, would address most of the water quality, terrestrial, and aquatic resources issues related to the Resighini Rancheria traditionally used resources (see Sections 3.2, 3.3, and 3.5).	2, 3	B (long term)	None
	5 (at Copco and Iron Gate Reservoirs only)	B (long term)	None
Construction of fishways at the four dams would address a portion of the critical issues related to migratory fish that were identified by the Resighini Rancheria; however the remaining critical issues affecting their traditionally used resources would persist (see Sections 3.2 and 3.3).	4	B (long term)	None

Table 5-2. Summary of Environmental Effects Relative to NEPA

Potential Impact	Alternative(s)	Effect Pursuant to NEPA	Mitigation
3.15 Socioeconomics			
Four Facilities			
Changes in annual O&M expenditures required to continue the operation of the existing facilities could affect employment, labor income, and output in the regional economy.	1, 4	NCFEC	None
	2, 3, 5	Adverse (long term)	None
Construction activities associated with dam removal and fish passage facilities would increase economic output, employment, and labor income during the construction period in Klamath and Siskiyou Counties.	2, 3, 4, 5	B (short term)	None
Mitigation spending after the deconstruction period could increase economic output, employment, and labor income in the regional economy.	2, 3, 4, 5	B (short term)	None
Commercial Fishing			
Changes in commercial fishing harvests could change fishing revenues and affect employment, labor income, and output in the regional economy.	1	NCFEC	None
	2, 3, 4, 5	B (long term)	None
Recreation			
Changes to reservoir recreation expenditures could affect jobs, labor income, employment, and output in the regional economy.	1, 5 (due to continued use of J.C. Boyle Reservoir)	NCFEC	None
	2, 3, 5 (due to removal of Copco and Iron Gate Reservoirs)	Adverse (long term)	None
Changes to in-river sport fishing opportunities could affect recreational expenditures and employment, labor income, and output in the regional economy.	1	NCFEC	None
	2, 3, 4, 5	B (long term)	None
Changes to ocean sport fishing could affect recreational expenditures in the regional economy.	1	NCFEC	None
	2, 3, 4, 5	B (long term)	None

Table 5-2. Summary of Environmental Effects Relative to NEPA

Potential Impact	Alternative(s)	Effect Pursuant to NEPA	Mitigation
Changes to whitewater boating opportunities could affect recreational expenditures and employment, labor income, and output in the regional economy.	1	NCFEC	None
	2, 3, 4, 5	Adverse (from reduced whitewater boating expenditures in the Upper Klamath River and Hell's Corner Reach)	None
<i>Indian Tribes</i>			
The continuation of dam operations could contribute to continuation and possible decline in the existing economic conditions of Indian Tribes in the area of analysis.	1	NCFEC	None
Dam removal and the construction of fish passage could increase fish harvest for subsistence, cultural practices and commercial uses and provide economically beneficial opportunities for Indian Tribes residing on the Klamath River (excluding the Hoopa Valley Tribe, who reside on the Trinity River).	2, 3, 4, 5	B (long term)	None
<i>PacifiCorp Hydroelectric Service</i>			
Energy rates for PacifiCorp customers could change.	1, 4, 5	UKN	None
Removal of the Four Facilities could result in increased energy rates for PacifiCorp customers.	2, 3	NCFEC	None

Table 5-2. Summary of Environmental Effects Relative to NEPA

Potential Impact	Alternative(s)	Effect Pursuant to NEPA	Mitigation
<i>Property Values and Local Government Revenues</i>			
Property values surrounding Iron Gate and Copco Reservoirs could change.	1, 4, 5 (around Copco 2 Reservoir)	NCFEC	None
	2, 3, 5 (around Copco 1 and Iron Gate Reservoirs)	Adverse (short term and long term)	None
Changes in real estate values around Copco 1 and Iron Gate Reservoirs could affect property tax revenues to Siskiyou County.	2, 3, 5	Adverse (short term); UKN ¹ (long term)	None
	4	NCFEC	None
Removal of the Four Facilities could affect property tax revenues to Siskiyou and Klamath Counties from PacifiCorp.	2, 3, 5	NCFEC	None
Construction worker spending could increase sales and use tax receipts in Siskiyou and Klamath Counties.	2, 3	B (short term)	None
Changes in visitation for recreation activities could affect sales tax revenues.	2, 3	UKN ²	None
<i>PacifiCorp's Property Taxes</i>			
PacifiCorp's property tax payments to Siskiyou and Klamath Counties could change.	1, 4	NCFEC	None
<i>Ongoing Restoration Activities</i>			
Ongoing restoration activities could generate employment, labor income, and output in the regional economy.	1, 4	NCFEC	None
<i>Irrigated Agriculture</i>			
Changes in Reclamation's Klamath Project hydrology could affect farm revenues, employment, labor income, and output in the regional economy.	1, 4	NCFEC	None
Changes in on-farm pumping costs could affect farm revenues, employment, labor income, and output in the regional economy.	1, 4	NCFEC	None

Table 5-2. Summary of Environmental Effects Relative to NEPA

Potential Impact	Alternative(s)	Effect Pursuant to NEPA	Mitigation
Water acquisitions could affect farm revenues, employment, labor income, and output in the regional economy.	1, 4	NCFEC	None
<i>Refuge Recreation</i>			
Changes in water supply could affect visitor spending for refuge recreation and affect employment, labor income, and output in the regional economy.	1, 4	NCFEC	None
<i>Tribal Program</i>			
Ongoing fisheries and conservation management by The Klamath Tribes, Karuk Tribe, and Yurok Tribe could generate employment, labor income, and output in the regional economy.	1, 4	NCFEC	None
<i>East and Westside Facilities – Programmatic Measure</i>			
Decommissioning of the East and Westside facilities could result in economic effects.	2, 3	NCFEC	None
<i>City of Yreka Water Supply Pipeline Relocation – Programmatic Measure</i>			
Construction activities associated with the Yreka Water Supply Pipeline could increase economic output, employment, and labor income during the construction period in Siskiyou County.	2, 3	B (short term)	None
<i>KBRA – Programmatic Measures</i>			
Fish habitat restoration for the Fisheries Program could affect employment, labor income, and output in the regional economy.	2, 3	B (during project implementation)	None
In the long term, the Fisheries Program could support increased fish abundance in the Klamath River and tributaries.	2, 3	B (long term)	None
Construction, analysis, and monitoring activities under the Water Resources Program could affect employment, labor income, and output in the regional economy.	2, 3	B (during project implementation)	None
Changes in Reclamation's Klamath Project hydrology could affect gross farm revenue and the regional economy.	2, 3	B (long term)	None
Increases in on-farm pumping costs could affect household income and reduce employment, labor income, and output in the regional economy.	2, 3	Adverse (long term)	None

Table 5-2. Summary of Environmental Effects Relative to NEPA

Potential Impact	Alternative(s)	Effect Pursuant to NEPA	Mitigation
Water acquisitions via permanent, voluntary water rights sales could affect farm revenues and employment, labor income, and output in the regional economy.	2, 3	B (long term)	None
Water acquisitions via short-term water leasing could decrease farm revenues and reduce employment, labor income, and output in the regional economy.	2, 3	Adverse (short term)	None
Changes in water supply could affect refuge recreation expenditures and employment, labor income, and output in the regional economy.	2, 3	B (long term)	None
Implementation of regulatory assurances under the KBRA could support employment, labor income, and output in the regional economy.	2, 3	B (short term) NCFEC (long term)	None
Implementation of the Klamath County Economic Development Plan could support long-term economic growth in Klamath County.	2, 3	B (long term)	None
If passed by voters, funds from the California Water Bond Legislation could be used by Siskiyou County to improve economic conditions in the county and to support future economic growth.	2, 3	B (long term)	None
Construction and monitoring activities associated with Tribal Program actions would increase jobs, labor income, and output for The Klamath Tribes, Karuk Tribe, and Yurok Tribe.	2, 3	B (short term)	None
3.16 Environmental Justice			
Continued impoundment of water at the reservoirs and declines in fisheries could disproportionately affect tribal people.	1	NCFEC	None
Dam removal and construction of fish passage facilities could affect fisheries and disproportionately affect tribal people.	2, 3, 4, 5	B (long term)	None

Table 5-2. Summary of Environmental Effects Relative to NEPA

Potential Impact	Alternative(s)	Effect Pursuant to NEPA	Mitigation
Increased traffic, air quality emissions, and noise associated with construction activities could disproportionately affect county residents and tribal people.	1	NCFEC	None
	2, 3, 4, 5	Disproportionate Effects (short term)	AQ-1: MY 2015 or newer engines for offroad construction equipment AQ-2: MY 2000 or newer engines for on-road construction equipment AQ-3: MY 2010 or newer engines for haul trucks AQ-4: Dust control measures during blasting operations NV-1: Noise and Vibration Control Plan

Table 5-2. Summary of Environmental Effects Relative to NEPA

Potential Impact	Alternative(s)	Effect Pursuant to NEPA	Mitigation
Release of sediment from reservoirs could cause disproportionate short-term impacts on county residents and tribal people.	1	NCFEC	None
	2, 3, 5	NCFEC (short term, inorganic and organic contaminants); Disproportionate Effect (short term, reduced mussel populations)	None
Changes to water quality could cause disproportionate long-term water quality impacts on county residents and tribal people.	1, 4, 5	NCFEC	None
	2, 3	B (long term)	None
Changes in county revenues could decrease county funding of social programs used by county residents.	1, 4	NCFEC	None
	2, 3, 5	Disproportionate Effects (long term)	None
Continued impoundment of water in the reservoirs and the installation of fish passage facilities could result in changes to water quality and fish populations which could disproportionately impact tribal health and social wellbeing in the long term.	1, 4, 5	NCFEC	None
	2, 3	B (long term)	None
Traffic on associated haul roads could disproportionately affect county residents and tribal people.	2, 3, 4, 5	Disproportionate Effects (short term); NCFEC (long term)	TR-1: Relocate Jenny Creek Bridge and Culverts
Dam removal activities and construction of fish passage could provide jobs for county residents and tribal people that are low income and minority.	2, 3, 4, 5	B (short term)	None
Removal of existing recreation facilities from the banks of the existing reservoirs could disproportionately affect county residents or tribal people.	2, 3	NCFEC	None
Keno Transfer			
The Keno Transfer could have adverse effects on environmental justice issues.	2, 3	NCFEC	None

Table 5-2. Summary of Environmental Effects Relative to NEPA

Potential Impact	Alternative(s)	Effect Pursuant to NEPA	Mitigation
East and Westside Facilities – Programmatic Measure			
The East and Westside Facilities decommissioning could have adverse effects on environmental justice issues.	2, 3	NCFEC	None
City of Yreka Water Supply Pipeline Relocation – Programmatic Measure			
The installation of the Yreka Water Supply Pipeline could disproportionately affect county residents or tribal people.	2, 3	NCFEC	None
KBRA – Programmatic Measures			
Implementation of the Phases I and II Fisheries Restoration Plans, the Fisheries Monitoring Plan, the Fisheries Reintroduction and Management Plan, and the Klamath River Tribes Interim Fishing Site could disproportionately affect tribal populations.	2, 3	B (long term)	None
Implementation of the Water Use Retirement Program, Off-Project Reliance Program, and Interim Flow and Lake Level Program could disproportionately affect low income and minority farm workers.	2, 3	Disproportionate Effects (short term); NCFEC (long term)	None
Implementation of the Tribal Fisheries and Conservation Management Program could disproportionately affect the tribes.	2, 3	B (long term)	None
Implementation of the Tribal Programs Economic Revitalization could disproportionately affect the tribes.	2, 3	B (long term)	None
Implementation of the Mazama Forest Project could disproportionately affect the tribes.	2, 3	B (long term)	None
Implementation of the Klamath County Economic Development Plan could disproportionately affect low income and minority people in Klamath County.	2, 3	B (long term)	None

Table 5-2. Summary of Environmental Effects Relative to NEPA

Potential Impact	Alternative(s)	Effect Pursuant to NEPA	Mitigation
Implementation of the California Water Bond Legislation could disproportionately affect low income and minority people in Siskiyou County.	2, 3	B (long term)	None

¹ Available data are insufficient to quantify such effects or to determine whether gains in riverine real estate values would be sufficient to offset the losses in reservoir values.

² Changes in recreation expenditures and associated sales taxes vary by recreation activity. The net effect of changes in recreation expenditures is unknown.

KEY:

Significance:

NCFEC = No Change From Existing Conditions

B = Beneficial

LTS = Less than Significant

S = Significant

N/A = Not Applicable

Alternatives:

1 = No Action/No Project

2 = Full Facilities Removal of Four Dams Alternative (Proposed Action)

3 = Partial Facilities Removal of Four Dams Alternative

4 = Fish Passage at Four Dams Alternative

5 = Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative

5.5 Significant and Unavoidable Impacts

Significant and unavoidable adverse effects refer to the environmental consequences of an action that cannot be avoided by redesigning the project, changing the nature of the project, or implementing mitigation measures. NEPA requires a discussion of any adverse impacts that cannot be avoided (40 CFR Section 1502.16). The CEQA Guidelines require a discussion on significant environmental effects that cannot be avoided as well as those that can be mitigated but not reduced to an insignificant level (Section 15126.2 (b) and Section 15126.2(a)). This section discusses the significant and unavoidable impacts of the Klamath River dam removal alternatives presented in Chapter 2, Project Description. For a summary of significant environmental effects that cannot be avoided relative to CEQA and NEPA see Table 5-3 (also Executive Summary, Table ES-4).

5.5.1 Water Quality

Short-term significant and unavoidable impacts would result from sediment release (and corresponding increases in suspended sediment concentrations [SSC]) associated with dam removal under the Proposed Action, the Partial Facilities Removal Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative. These short term (<2 years following dam removal) increases in SSCs would result in a significant impact in the Hydroelectric Reach downstream from J.C. Boyle Dam. In the Lower Klamath Basin, sediment release from dam removal under the Proposed Action, the Partial Facilities Removal Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative would result in non-attainment of applicable North Coast Basin Plan water quality objectives for suspended material in the lower Klamath River and the Klamath Estuary and would substantially adversely affect the cold freshwater habitat (COLDFRESH) beneficial use. Thus, these short-term increases in SSCs would be significant and unavoidable in the lower Klamath River and the Klamath Estuary.

Dissolved oxygen impacts are anticipated to be secondary impacts of the sediment release during reservoir drawdown. Under the Proposed Action, the Partial Facilities Removal Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative, elevated SSCs during reservoir drawdown and dam removal would result in increases in oxygen demand and reductions in dissolved oxygen in the Hydroelectric Reach downstream from J.C. Boyle Reservoir and in the lower Klamath River from Iron Gate Dam to Clear Creek. These decreases in dissolved oxygen would be significant and unavoidable impacts.

5.5.2 Aquatic Resources

Under the Proposed Action, Partial Facilities Removal Alternative, and Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative, elevated levels of SSC during the 2 to 3 month reservoir drawdown period would result in short-term

significant and unavoidable impacts on critical habitat for coho salmon as well as essential fish habitat for Chinook and coho salmon.

Suspended sediment concentrations and bedload sediment transport and deposition under the Proposed Action, the Partial Facilities Removal Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative would result in the short-term substantial reduction in the abundance of a year class of coho salmon (Upper Klamath River, Mid-Klamath River, Shasta River, and Scott River population units), summer and winter steelhead, Pacific Lamprey, green sturgeon, freshwater mussels, and benthic macroinvertebrate individuals present in the mainstem after reservoir drawdown in January 2020. Based on the reduction in the abundance of a year class in the short-term, the loss of these individuals during short-term increases in SSC and bedload movement would be significant and unavoidable.

5.5.3 Algae

The Proposed Action, the Partial Facilities Removal Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative¹ dam removal, conversion of the reservoir areas to a free-flowing river, and the elimination or reduction of hydropower peaking operations could cause long-term increases in nuisance periphyton growth due to increases in available habitat along low-gradient channel margin areas downstream from J.C. Boyle Dam; this impact would be significant and unavoidable.

While nutrient increases in this reach would be less than significant following full attainment of the Oregon and California TMDLs (Section 3.2.4.3.2.3), removal of the reservoirs and elimination of hydropower peaking operations in the J.C. Boyle Peaking Reach would immediately provide additional low-gradient habitat suitable for periphyton. The particular periphyton species that may become abundant in these areas are unknown (E. Asarian, pers. comm., 2011). The overall effect of the Proposed Action would likely be to increase periphyton in the re-exposed margins of low gradient river channels in the Hydroelectric Reach until full attainment of the Oregon and California TMDLs can be achieved.

5.5.4 Air Quality

Under the Proposed Action and Partial Facilities Removal Alternatives, total emissions of Particulate Matter <10 microns (PM₁₀) from construction equipment exhaust, on-road haul trucks, commuting vehicles, and fugitive dust emissions from unpaved roads and general earth moving activities would exceed Siskiyou County's thresholds of significance. This impact could not be mitigated to less than significant with implementation of the mitigation measures in Section 3.9, Air Quality, and would remain a significant and unavoidable impact.

¹ This revision reflects an editorial clarification. As indicated by the analysis under the Proposed Action, the determination for Alternative 5 in the Hydroelectric Reach from Copco 1 Reservoir to Iron Gate Reservoir should also have been a significant effect.

Construction activities associated with the KBRA programs under the Proposed Action and Partial Facilities Removal Alternative could result in temporary increases in air quality pollutant emissions from vehicle exhaust and fugitive dust. These short-term impacts would be significant and unavoidable. Mitigation Measures AQ-1, 2, and 3 would be implemented to reduce the severity of these effects to a less than significant level; however, emissions from any construction actions completed in the same year as hydroelectric facility removal actions may not be reduced to a less than significant level. Additionally, operational activities associated with the Fisheries Reintroduction and Management Plan could result in short-term increases in air quality pollutant emissions from vehicle exhaust associated with trap-and-haul activities. While implementation of mitigation measures in Section 3.9, Air Quality would reduce the severity of these impacts to less than significant, emissions from any construction actions completed in the same year as hydroelectric facility removal actions may not be reduced to a less than significant level.

5.5.5 Greenhouse Gases/Global Climate Change

Implementation of the Proposed Action and decommissioning and removal of Iron Gate, Copco 1, and Copco 2 dams (which are California Renewable Portfolio Standard [RPS]-eligible facilities) is contrary to implementation of AB 32 but the significance would diminish as new renewable sources are developed. Although it is expected that PacifiCorp would add new sources of renewable power that would replace the removed dams, the analysis in Section 3.10, Greenhouse Gases/Global Climate Change, provides a conservative assumption that emissions could still occur when the dams are removed.

Section 3.10, Greenhouse Gases/Global Climate Change, describes that the California Air Resources Board expects that implementation of its Scoping Plan (2008) would reduce 21.3 million metric tons carbon dioxide equivalent by 2020 (from 2005 baseline) from California's RPS; therefore, the possible increase in emissions from removing the dams would account for three percent of the expected emissions reduction. Under a business-as-usual scenario, which assumes that the Scoping Plan would not be implemented, this would impede California's ability to meet its emission reduction goal. While mitigation measures in Section 3.10, Greenhouse Gases/Global Climate Change, would be implemented to reduce emissions from power replacement, it is expected that greenhouse gas emissions would remain significant and unavoidable in the short term until PacifiCorp adds new sources of renewable power that would replace the removed dams. Implementation of the Partial Facilities Removal Alternative, the Fish Passage at Four Dams Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative would also result in the reduced operation or decommissioning of the power generating facilities of the dams; thus, electricity generation capacity would require replacement with other sources of power.

5.5.6 Cultural and Historic Resources

Under the Proposed Action, the Partial Facilities Removal Alternative, the Fish Passage at Four Dams Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative some, if not all, of the Four Facilities and their

associated hydroelectric facilities would be removed or altered. These facilities are part of the Klamath Hydroelectric Historic District (KHHD), which is eligible for the National Register of Historic Places. Removal of these structures constitutes a significant and unavoidable impact.

Implementation of the following KBRA programs would include ground disturbing activities that are likely to have a significant impact on cultural and historic resources that are eligible for inclusion on the National Register and/or California Register. These KBRA programs include:

- Phases 1 and 2 Fisheries Restoration Plans
- Fisheries Reintroduction and Management Plan
- Wood River Wetland Restoration Project
- On-Project Plan
- Water Use Retirement Program
- Fish Entrainment Reduction
- Klamath Tribes Interim Fishing Site
- Mazama Forest Project

Studies will be conducted to identify cultural resources and measures to reduce significant impacts to those resources. As described in Section 3.13, Cultural and Historic Resources, implementation of specific plans and projects associated with Phase 1 and 2 Fisheries Restoration will require future environmental compliance as appropriate. While Mitigation Measures CHR-1, CHR-2, CHR-3, and CHR-4 would be implemented, these impacts would remain significant and unavoidable.

5.5.7 Scenic Quality

Ongoing fish habitat restoration actions would occur under the No Action/No Project Alternative throughout the entire basin with the exception of the Trinity River Basin. Activities related to these actions including floodplain rehabilitation, large woody debris replacement, fish passage correction, and cattle exclusion fencing, among others would include construction activities which could result in short-term significant impacts on scenic resources. These impacts would be significant and unavoidable in the short term.

Implementation of the Proposed Action, the Partial Facilities Removal Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative would result in the removal of some historic properties. While the removal of buildings in and return to a natural landscape is preferable under the Bureau of Land Management's (BLM) Visual Resource Management (VRM) process, some historic scenery elements may be considered socially valued and their elimination from the scenic character would be considered a significant and unavoidable scenery impact of the project.

In addition to the removal of historic properties, removal of dams and reservoirs would result in substantial changes in the former reservoir areas during drawdown and until restoration is complete. Receding water in the current reservoirs would expose reservoir sediment. It is expected that the river channel would appear very similar to conditions

before the river was impounded (with exception of vegetation not yet being established). The alternatives would involve stabilizing and revegetating the newly exposed reservoir areas with herbaceous and woody vegetation. Until the restoration was complete, however, the area would appear barren and/or sparsely vegetated. Additionally, Section 3.19, Scenic Quality, describes that studies estimate that it will take 30 years for the river corridor habitats to fully recover from the dam removals (Phillip Williams and Associates [PWA] 2009). Thus, these impacts on scenic resources would be significant and unavoidable in both the short term and long term.

Sediment release during reservoir drawdown would also result in temporary significant and unavoidable impacts to water aesthetics (clarity, turbidity (depth of view), and color). The impact on the appearance of the Klamath River would be temporary; however, as no mitigation measures could be implemented to reduce the impact on scenic resources, it would be significant and unavoidable. Deconstruction, restoration, and construction activities associated with the Proposed Action, the Partial Facilities Removal Alternative, the Fish Passage at Four Dams Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative would result in areas around the dams and in the vicinity of construction being inconsistent with the surrounding natural landscape and the VRM classification. Specifically, scenic quality changes during deconstruction, restoration, and construction activities (including the potential replacement of the existing wooden Lakeview Bridge just downstream from Iron Gate Dam with a concrete bridge and the relocation of existing recreation facilities under the Proposed Action and the Partial Facilities Removal Alternative) would be caused by the temporary presence of large construction vehicles and equipment, temporary structures, temporary access roads, equipment storage areas, material stockpiles, piles of demolition materials, and other common construction items that would detract from the natural surroundings. These temporary impacts on scenic resources would be significant and unavoidable.

The addition of the fishways, under the Fish Passage at Four Dams Alternative and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative, would change the scenic character in the vicinity of the dams by adding hardscape elements that would blend with the facility features but would not blend with the natural landscape and could dominate views due to their size. At Copco 1 and Iron Gate Dams, the fishway structures would be particularly large (see Table 3.19-3 in Section 3.19, Scenic Quality). Although the fishways have not yet been designed, they likely could display angular geometry, continuous straight lines, and flat surfaces that may moderately contrast with the colors, forms, and textures of the surrounding characteristic landscape, or may be insignificant compared to scenery impacts of the existing dam facilities. Thus, the addition of fishways could be a significant, permanent impact. No mitigation measures could be implemented to lessen the impact on scenic quality.

Under the Proposed Action, the Partial Facilities Removal Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative, construction of a new, elevated City of Yreka Water Supply Pipeline and steel pipeline

bridge to support the pipe above the river could result in short-term and long-term impacts significant and unavoidable impacts on scenic resources.

Construction activities associated with fish collection facilities as part of the Fisheries Reintroduction and Management Plan of the KBRA would introduce new features into the landscape. Facilities required for trap and haul operations would result in impacts on scenic resources at Keno and Link River Dams. This would result in a long-term significant and unavoidable impact on scenic quality.

5.5.8 Recreation

Under the Proposed Action, the Partial Facilities Removal Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative, the Hell's Corner Reach of the Klamath River, which currently provides whitewater boating opportunities, would lose acceptable and predictable flows necessary for whitewater boating. Decreases in the number of days with acceptable flows for whitewater boating would be a significant and unavoidable impact in the Hell's Corner Reach. Loss of the predictable peaking flows in the J.C. Boyle Peaking Reach under the Fish Passage at Four Dams Alternative and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative would inhibit the ability of commercial outfitters to provide whitewater boating opportunities on a regular scheduled basis. This water flow impact on whitewater boating opportunities would be a significant and unavoidable impact.

5.5.9 Noise and Vibration

Construction activities at the Copco 1 Development associated with the Proposed Action, the Partial Facilities Removal Alternative, the Fish Passage at Four Dams Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative would produce noise and vibration levels resulting in significant and unavoidable impacts that could affect sensitive receptors in the area. Noise impacts would be significant and unavoidable for outdoor receptors during construction.

Construction activities at Iron Gate Dam would cause temporary increases in nighttime noise levels for the Proposed Action, the Partial Facilities Removal Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative resulting in a significant and unavoidable impact. Reservoir restoration activities in the vicinity of the dams and reservoirs would also result in short-term increases in noise levels. Impacts related to vibration produced during construction activities under the Proposed Action, the Partial Facilities Removal Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative would be significant and unavoidable. These short-term noise and vibration impacts would remain significant and unavoidable even after implementation of the mitigation measure in Section 3.23, Noise and Vibration.

Table 5-3. Summary of Significant Environmental Effects that Cannot be Avoided Relative to CEQA and NEPA

Potential Impact	Alternative(s)	Significance Pursuant to CEQA	Proposed Mitigation	Significance After Mitigation Pursuant to CEQA
3.2 Water Quality				
<i>Suspended Sediments</i>				
Upper Klamath Basin				
Draining the reservoirs and release of sediment could cause short-term increases in suspended material in the Hydroelectric Reach downstream from J.C. Boyle Dam.	2, 3, 5	S (short term)	None	S (short term)
Lower Klamath Basin				
Draining the reservoirs and release of sediment could cause short-term increases in suspended material in the lower Klamath River and the Klamath Estuary.	2, 3, 5	S (short term)	None	S (short term)
<i>Dissolved Oxygen</i>				
Upper Klamath Basin				
Draining the reservoirs and release of sediment could cause short-term increases in oxygen demand (Immediate Oxygen Demand [IOD] and Biological Oxygen Demand [BOD]) and reductions in dissolved oxygen in the Hydroelectric Reach downstream from J.C. Boyle Reservoir.	2, 3, 5	S (short term)	None	S (short term)
Lower Klamath Basin				
Dam removal and sediment release could cause short-term increases in oxygen demand (Immediate Oxygen Demand [IOD] and Biological Oxygen Demand [BOD]) and reductions in dissolved oxygen in the lower Klamath River, the Klamath Estuary, and the marine nearshore environment.	2, 3, 5	S - (short term) lower Klamath River from Iron Gate Dam to Clear Creek	None	S – (short term) lower Klamath River from Iron Gate Dam to Clear Creek

¹ Periphyton are algae that grow attached to rocks and other substrates on a riverbed. Although sometime these species cause nuisance conditions, they are rarely considered toxic. Increased non-toxic periphyton biomass would not lead to increases in algal toxins in the Klamath River. Blooms of phytoplankton (suspended algae) occurring in the calm, lake-like waters are responsible for the production of algal toxins, such as microcystin, in the Klamath River downstream from Iron Gate Dam. Noxious phytoplankton would not thrive in the free flowing river following dam removal.

² An editorial clarification was made to this determination for Alternative 5 in Section 3.4, Algae. As indicated by the analysis under the Proposed Action in Section 3.4, Algae, the determination for Alternative 5 in the Hydroelectric Reach from Copco 1 Reservoir to Iron Gate Reservoir should also have been a significant effect.

³ While Mitigation Measures AQ-1, 2, and 3 would be implemented to reduce impacts to LTS, emissions from any construction actions completed in the same year as hydroelectric facility removal actions may not be reduced to a less than significant level. Implementation of specific plans and projects described in the KBRA will require future environmental compliance as appropriate.

⁴ Studies will be conducted to identify cultural resources and reduce significant impacts to these resources. Implementation of specific plans and projects associated with the KBRA will require future environmental compliance as appropriate.

5.6 Adverse Environmental Effects After Mitigation Relative to NEPA

Significant environmental effects that are adverse after mitigation are environmental effects of an action that cannot be avoided by redesigning the project, changing the nature of the project, or implementing mitigation measures. NEPA regulations require a discussion of any adverse impacts that cannot be avoided as a result of the Proposed Action (40 Code of Federal Regulations Part 1502.16). NEPA also requires a discussion of means to mitigate adverse impacts. These impacts are summarized in Table 5-3 for the purposes of NEPA and CEQA. Table 5-4 summarizes the adverse environmental impacts of the resources analyzed in this EIS/EIR specific to NEPA including Socioeconomics and Environmental Justice resources.²

5.6.1 Socioeconomics

Under the Proposed Action, the Partial Facilities Removal Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative, reduced annual operations and maintenance (O&M) expenditures required to continue the operation of the dams and existing facilities could affect employment, labor income, and output in the regional economy. These reductions in O&M expenditures would result in long-term adverse effects in the regional economy.

The Proposed Action, the Partial Facilities Removal Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative would result in reduced reservoir recreation opportunities associated with dam and reservoir removal and could reduce recreational expenditures in the regional economy. If visitors prefer to recreate in a reservoir setting rather than the new river setting, they may choose to recreate outside of the region. Losses in recreation spending would directly affect several industries in the region and would result in secondary impacts on support industries. In addition, implementation of any of these three dam removal alternatives would result in loss of jobs and incomes for PacifiCorp workers employed in Siskiyou and Klamath Counties.

Another adverse effect would result from losses in whitewater boating opportunities under the Proposed Action and the Partial Facilities Removal Alternative. Specifically, flow decreases in the Hell's Corner Reach would result in losses of commercial trips and corresponding losses in recreation expenditures in the local economy.

Dam removal and the removal of Copco 1 and Iron Gate Reservoirs under the Proposed Action, Partial Facilities Removal Alternative, and Fish Passage at J.C. Boyle and

² Effects relative to tribal trust resources are not displayed in this table given that no new adverse effects were identified relative to the alternatives analyzed in this EIS/EIR. Section 3.12, Tribal Trust, of this EIS/EIR does, however, summarize the existing and ongoing tribal trust impacts present in the Klamath Basin.

Release of sediment from reservoirs could cause disproportionate short term impacts on county residents and tribal people.	2, 3, 5	Disproportionate Effect (short term)	None
Changes in county revenues could decrease county funding of social programs used by county residents.	2, 3, 5	Disproportionate Effects	None
Traffic on associated haul roads could disproportionately affect county residents and tribal people.	2, 3, 4, 5	Disproportionate Effects (short term)	TR-1: Relocate Jenny Creek Bridge and Culverts
KBRA – Programmatic Measures			
Implementation of the Water Use Retirement Program, Off-Project Reliance Program, and Interim Flow and Lake Level Program could disproportionately affect low income and minority farm workers.	2, 3	Disproportionate Effects (short term)	None

¹ Effects relative to tribal trust resources are not displayed in this table given that no new adverse effects were identified relative to the alternatives analyzed in this EIS/EIR. Section 3.12, Tribal Trust of this EIS/EIR does however summarize the existing and ongoing tribal trust impacts present in the Klamath Basin.

² Available data are insufficient to quantify such effects or to determine whether gains in riverine real estate values would be sufficient to offset the losses in reservoir values.

³ Changes in recreation expenditures and associated sales taxes vary by recreation activity. The net effect of changes in recreation expenditures is unknown.

KEY:

Significance:

NCFEC = No Change From Existing Conditions

B = Beneficial

LTS = Less than Significant

S = Significant

N/A = Not Applicable

Alternatives:

1 = No Action/No Project

2 = Full Facilities Removal of Four Dams Alternative (Proposed Action)

3 = Partial Facilities Removal of Four Dams Alternative

4 = Fish Passage at Four Dams Alternative

5 = Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative

Copco 2, Remove Copco 1 and Iron Gate Alternative would affect private parcels with partial reservoir views, frontage/access or with river views subsequent to the action (Bender Rosenthal, Inc. 2011 and 2012). While a majority of the applicable private parcels are vacant residential land and single-family residential, changes caused by dam removal would have adverse effects on property values in the short term. However, the net magnitude of these changes is difficult to forecast. In the long term, land values of parcels downstream from Iron Gate Dam with river views could increase because of restoration of the river, including improved water quality and more robust anadromous fish runs. Along the same lines, if some land values are reduced and there are no offsetting increases in other property values, Siskiyou County property tax revenues might decline relative to the No Action/No Project Alternative, assuming nothing else changes that might impact property tax revenues, (e.g., tax rates). This would result in a short-term adverse impact.

Under the KBRA, increases in on-farm pumping costs would affect household income and reduce employment, labor income, and output in the regional economy. Under the Proposed Action and the Partial Facilities Removal Alternative, irrigators are pumping more ground water compared to the No Action/No Project Alternative and therefore are paying more for electricity under the Proposed Action and Partial Facilities Removal even with a decrease in electricity rates assumed in the Proposed Action (Reclamation 2012a and Reclamation 2012b). Thus, a reduced household income due to increased pumping costs would have a relatively small adverse impact on the regional economy.

Water acquisitions via short-term water leasing, which could occur as part of KBRA programs like the Off-Project Reliance Program and the Interim Flow and Lake Level Program, could decrease farm revenues and reduce employment, labor income, and output in the regional economy. These programs allow farmers to sell or lease their water for fisheries programs on a short-term basis when sufficient water is unavailable for fish. The regional economy would be affected by the loss in gross farm revenue generated on the land idled by farmers who voluntarily lease water. While some of these regional effects would be offset by household induced effects when farmers spend a portion of the compensation in the local area, short-term water leasing proposed in the KBRA is expected to have a short-term, adverse effect on the regional economy.

5.6.2 Environmental Justice

Implementation of the Proposed Action, the Partial Facilities Removal Alternative, the Fish Passage at Four Dams Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative would result in short-term construction-related impacts to air quality, traffic (including traffic on associated haul roads used during construction), and noise. These effects would result in short-term disproportionate effects to Siskiyou and Klamath County residents and tribal people. In addition, sediment release during reservoir drawdown under the Proposed Action, the Partial Facilities Removal Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove

Copco 1 and Iron Gate Alternative would result in reduced freshwater mussel populations which would disproportionately affect tribes that rely on the mussels as a food source. This would be a short-term disproportionate effect to tribal people.

Section 3.15, Socioeconomics, describes that the Proposed Action, the Partial Facilities Removal Alternative, and the Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative would cause short-term and long-term declines in tax revenues to the counties in the area of analysis stemming from a discontinuation of tax revenue from PacifiCorp and a short-term decrease in property values near the reservoirs. Reductions in the counties' budgets and resulting reductions or eliminations in social programs would disproportionately affect low income and minority county residents and tribal people.

Under the KBRA, implementation of the WURP, Off-Project Reliance Program, and Interim Flow and Lake Level Program could result in voluntary land fallowing and permanent water right sales. In turn, farm labor jobs could be lost which could disproportionately affect low-income, minority farm workers, who could lose a portion of their income if farms no longer required their labor. These would be short-term disproportionate effects.

5.7 Synopsis of Major Impacts and Benefits of the Alternatives

This section presents a synopsis of major impacts and benefits for each alternative with a focus on aquatic resources and water quality. (All of the significant adverse impacts that cannot be avoided for all resource categories are listed in Table 5-3 and Table 5-4). This summary section presents impacts and benefits incrementally to illustrate potential key benefits and impacts that may occur under each alternative. Though impacts to all resources will ultimately be considered by the Secretary of the Interior when making the Determination on whether or not the Proposed Action is in the public interest, this summary focuses on restoring fisheries and improving water quality (fishery and water quality benefits are also summarized in Table 5-5 (also Executive Summary, Table ES-6)). A synthesis of this information is particularly important to address the question of whether and to what degree an alternative may advance the restoration of the salmonid fisheries of the Klamath Basin and to determine which alternative may be environmentally preferable. In addition, the Affected Environment/Existing Conditions is summarized because it is a valuable point of comparison. (For more detail on each alternative and how alternatives were selected refer to ES.5 Alternatives Development and Chapter 2 Proposed Action and Description of Alternatives).

The structure of the section is as follows:

- Affected Environment/Existing Conditions;
- Alternative 1 (No Action/No Project Alternative);
- Alternative 4 (Fish Passage at Four Dams Alternative);

- Alternative 5 (Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate);
- Alternatives 2 (Full Facilities Removal of Four Dams (Proposed Action)) and 3 (Partial Removal of Four Dams);
- Comparison of Alternative 2 and 3

Under NEPA (40 CFR Part 1502.16, Environmental Consequences), a discussion of the environmental impacts of the alternatives, including the Proposed Action, should be included. A discussion of the potential beneficial effects of the alternatives is also valuable for decisionmakers when comparing and contrasting alternatives and determining the best course of action.

CEQA Guidelines require the balancing, as applicable, of the economic, legal, social, technological, or other benefits of a proposed project against its unavoidable environmental risks when determining whether to approve a project (Section 15093 (a)-(c)). If the specific benefits, including region-wide or Statewide environmental benefits of a proposed project outweigh the unavoidable adverse environmental effects, the adverse environmental effects may be considered “acceptable.” When a Lead Agency approves a project which will result in the occurrence of significant effects which are identified, but not avoided or substantially lessened, the Lead Agency under CEQA shall state in writing the specific reasons to support its action based on the Final EIS/EIR or other information in the record. This statement becomes the statement of overriding considerations as required under CEQA.

As illustrated throughout this Executive Summary, many measures agreed upon in the KHSA and KBRA centered on improving and resolving issues of low or declining fish populations and fisheries, inadequate water supplies, and degraded water quality. The primary goal of these agreements is to improve the condition and reliability of these basin resources and thereby benefit the communities who rely on them, or historically depended on them, for a way of life. This includes tribal, fishing, farming, and recreational communities throughout the Klamath Basin.

One example of the inter-relatedness of basin resources and communities can be illustrated by evaluating the impacts and benefits of the alternatives on tribal communities where environmental justice is a concern. Reversing the consequences of barriers to fish passage, degraded fish habitat, and degraded water quality throughout the basin could result in great benefit to tribal communities relying on fish, shellfish, riparian plants, clean water, and other resources for their subsistence, ceremonies, physical health, way of life, and spiritual well-being. While sediment release and other construction related activities during dam removal could cause short term (1 to 2 years) adverse impacts on fisheries downstream from the Hydroelectric Reach, salmon and other aquatic resources would be expected to return to population levels observed prior to dam removal (in 2010 when the Notice of Preparation was issued) within 5 years, and would provide long-term benefits to Indian Tribes for 50 years and beyond (these effects for Indian Tribes are analyzed in Section 3.16).

Because restoring fisheries, improving water quality, and helping communities are major goals of the Proposed Action and of the action alternatives, the major long-term benefits and impacts of each alternative are summarized below relative to these goals.

5.7.1 Existing Conditions/Affected Environment

The Klamath Basin currently suffers from degraded fisheries, excessive exposure of salmon to disease, degraded habitat quality (including altered flows, water temperatures, river channel structure, and invasive species), blocked access to historical habitat, and degraded water quality (including problems with dissolved oxygen, pH, nutrient enrichment, algal growth, and algal toxins). Major water quality problems exist in Upper Klamath Lake, Keno Impoundment/Lake Ewauna, and the reservoirs in the Hydroelectric Reach, as well as the Lower Klamath Basin downstream from Iron Gate Dam.

Results of these impaired water quality and habitat conditions include fish die-offs, listings under ESA and the California Endangered Species Act (CESA), health advisory postings for algal toxins in Copco 1 and Iron Gate reservoirs since 2005, and commercial fishing closures. Circumstances for salmonid fisheries and threatened and endangered species in the Klamath Basin are not improving. In addition, basin water supplies are over-allocated and do not meet all user needs; these challenges have been particularly acute in dry years. Water shortages, combined with the need to provide water to address the needs of ESA-listed species (suckers in Upper Klamath Lake and coho salmon in the Klamath River), national wildlife refuges, and farming communities have led to the reduction of irrigation water deliveries to farmers in dry years. In short, existing conditions represent a continued hardship for fishing, farming, tribal, and recreational communities. In particular, the Klamath Tribes have had to bear the hardship of being without salmon in the Upper Basin for nearly 100 years and without harvestable sucker populations for 25 years; these species are fundamental to their diet, their ceremonies, and their cultural well-being.

5.7.2 Alternative 1 (No Action/No Project Alternative)

Alternative 1 (No Action/No Project Alternative) is continued operation of the Klamath Hydroelectric Project under an annual license issued by FERC and would result in the continuation of many of the conditions described under Existing Condition/Affected Environment. This alternative would continue to block anadromous fish access to over 420 miles of historical habitat, including low gradient habitat of critical importance to spawning and rearing under Copco 1 and Iron Gate reservoirs. Also, access to cold water springs (areas of ground water discharge), particularly in the Upper Basin, would continue to be blocked. These cold water springs offer some protection to aquatic species against the future changes associated with climate change and improve winter growth opportunities for rearing fish. Disease issues related to crowding of fish below Iron Gate Dam, atypically stable flows, disrupted sediment transport processes, and over abundance of an intermediate hosts for fish disease would persist. Iron Gate hatchery juvenile production as mitigation for 16 miles of habitat loss would continue, but also exacerbates fish disease issues. For resident fish in the Hydroelectric Reach, the current adverse effects of peaking and those of entrainment into hydroelectric facilities would continue.

Implementation of TMDLs in Oregon and California over the next 50 years would be expected to help alleviate some of basin-wide water quality problems, although the implementation and timing of TMDL-related actions is unknown and effective improvements could take decades to achieve. Furthermore, to date there are no proposed management actions that would achieve the temperature allocations assigned to Copco 1 and Iron Gate reservoirs under the TMDLs. The effects of climate change over the next 50 years could dampen potential benefits from TMDLs, which would continue current conditions responsible for depressed populations of certain species like Chinook or steelhead and would reduce opportunities to improve survival of ESA-listed fish.

As the FERC relicensing process would continue following a Negative Determination on dam removal from the Secretary, Alternative 1 is not likely to continue as the status quo; however, if a new long-term FERC license is issued, it would be contingent on facility operations being compliant with all other applicable laws and regulations, including the Clean Water Act and the Endangered Species Act, making it difficult to predict when a new license might be implemented. For this analysis, the assumption for the next 50 years is that all the dams and the associated reservoirs remain and continue to operate under annual licenses and without construction of any new fish passage facilities. This would preserve the existing hydroelectric power generation capacity and allow use of reservoirs and peaking flows for recreational purposes (the significance of these effects is analyzed in Sections 3.18 and 3.20, respectively). The recreational value of these reservoirs, however, has been diminished in recent years (since 2005) due to the documented growth of toxic algae in Copco 1 and Iron Gate reservoirs and health advisory postings to that effect, a condition that can be expected to persist in the future without significant progress on nutrient reduction in the reservoirs such as through the TMDL process.

Alternative 1 would not result in the short-term negative impacts related to construction activities or short-term impacts to fish from the downstream transport of sediment during reservoir drawdown. Also Alternative 1 does not include the full implementation of KBRA. The ongoing resource management activities, ongoing Interim Measures, TMDLs, biological opinions, and other regulatory conditions described for this alternative would also occur under Alternatives 2, 3, 4, and 5.

5.7.3 Alternative 4 (Fish Passage at Four Dams Alternative)

Alternative 4 would require the long-term licensure of the Hydroelectric Project by FERC to a Hydropower Licensee; although, it is assumed that operations of the Four Facilities would change in response to DOI mandatory flow conditions and DOC and DOI fishway prescriptions. Alternative 4 would eventually result in the same benefits to water quality from TMDL implementation as Alternative 1; however the same limitations on achieving water quality objectives in the Hydroelectric Reach and downstream also apply. Specifically, there are no proposed management actions that would achieve the temperature allocations assigned to Copco 1 and Iron Gate reservoirs under the TMDLs, and control of toxic blooms of cyanobacteria would not be expected to diminish in the future without significant progress on nutrient reduction in the reservoirs, which could

take decades to achieve. The creation of volitional fish passage for salmonids at each of the Four Facilities under this alternative would provide access to at least 420 miles of historical habitat above Iron Gate Dam to anadromous fish. Consequently, the size and diversity of these populations would increase. Implementation of Alternative 4 and access to Upper Basin habitat would reduce the concentration of fish carcasses which are linked to the transmission of fish disease from adult salmon to juvenile salmon. In addition, fish would gain access to cold water springs, particularly in the Upper Basin, offering some protection against the predicted future changes associated with climate change and improved winter growth opportunities for rearing fish. The adverse effects of peaking would be largely eliminated (only one day a week) and those of entrainment into hydroelectric facilities would be largely eliminated.

Iron Gate Hatchery would continue to mitigate for the loss of production of salmonids from the 16 miles of habitat lost between Iron Gate and Copco 2 dams.

NOAA Fisheries Service and DOI prescriptions include a measure to trap and haul fall-run Chinook salmon upstream and downstream around Keno Impoundment. The prescriptions call for seasonal trap and haul operations from June 15 to November 15 when water quality conditions are not suitable for fish (dissolved oxygen concentration less than 6 mg/l or temperature above 20 degrees Celsius) (DOI 2007; NOAA Fisheries Service 2007).

For this analysis over the next 50 years, Alternative 4 retains the majority (80%) of hydroelectric power generation capacity and project reservoirs would remain in place and would continue to be used for recreational purposes (the significance of these effects is analyzed in Sections 3.18 and 3.20, respectively). Alternative 4 would not result in short-term impacts to fish from downstream transport of sediment during reservoir drawdown and dam removal.

5.7.4 Alternative 5 (Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate)

Alternative 5 would result in the same benefits as Alternative 4 for anadromous fish; however, removal of Copco 1 and Iron Gate Dams would provide additional benefits. Fish would be able to migrate upstream and downstream more efficiently through a greater length of natural river channel and through fewer constructed fish passage facilities to use habitat in the Upper Basin. Alternative 5 would create access to at least 420 miles of historical habitat above Iron Gate Dam for anadromous fish. This would include access to low gradient historical habitat of critical importance to spawning and rearing under Copco 1 and Iron Gate Reservoirs. This additional habitat would facilitate greater dispersion of spawning adult salmonids than under Alternative 4, thereby reducing the incidence of disease. Disease risks to resident fish would be low and the establishment of a disease hot spot for *C. shasta* above the current location of Iron Gate Dam would be unlikely. In addition, fish would gain access to cold water springs, particularly in the Upper Basin, offering improved winter growth opportunities for

rearing fish and some protection against future changes associated with climate change. The adverse effect of peaking flows, stranding, and entrainment of fish into hydroelectric facilities would also be eliminated.

The Hydropower Licensee would continue to fund operating Iron Gate Hatchery to meet current mitigation requirements until Iron Gate Dam is removed, after which time the hatchery would not be funded by Hydropower Licensee and is assumed to be closed.

NOAA Fisheries Service and DOI prescriptions would also be applicable to Alternative 5. Therefore Alternative 4 and 5 include a measure to trap and haul fall-run Chinook salmon upstream and downstream around Keno Impoundment. The prescriptions call for seasonal trap and haul operations from June 15 to November 15 when water quality conditions are not suitable for fish (dissolved oxygen concentration less than 6 mg/l or temperature above 20 degrees Celsius) (DOI 2007; NOAA Fisheries Service 2007).

By removing the two largest reservoirs in the Hydroelectric Reach, many of the water quality impairments caused by impounding water, including high pH, altered patterns for water temperatures, elevated water temperatures in the fall, low dissolved oxygen, and the presence of algal toxins, would be largely eliminated within and below the Hydroelectric Reach.

While water quality problems would improve as a result of draining Copco 1 and Iron Gate reservoirs, Alternative 5 would also eliminate recreational uses such as flatwater fishing in these reservoirs and could decrease the value of property with access to, or views of, the reservoirs. Decreased recreational opportunities could have related effects on other resources analyzed in this EIS/EIR (i.e., Socioeconomics and Recreation, analyzed in detail in Sections 3.15 and 3.20, respectively).

The release of sediments stored behind Copco 1 and Iron Gate dams would have negative impacts on fish and water quality in the short term (< 2 years) but would provide longer term benefits in the form of increased habitat complexity and increased movement of larger sediment substrate along the river bed (bedload transport), reductions in fish disease, and the nearly complete elimination of toxic algal blooms in the Hydroelectric Reach and downstream. Some chemicals are present in reservoir sediments at concentrations below critical screening levels for freshwater and marine disposal and do not preclude sediment release downstream.

Removal of Copco 1 and Iron Gate dams and the loss of peaking flows at J.C. Boyle Dam would significantly decrease the amount of hydroelectric power generated by the Klamath Hydroelectric Project. However this alternative does maintain reservoir recreation opportunities at J.C. Boyle Reservoir.

5.7.5 Alternatives 2 (Full Facilities Removal of Four Dams [Proposed Action]) and Alternative 3 (Partial Removal of Four Dams)

Alternatives 2 and 3 would have the benefits of Alternatives 4 and 5 for anadromous fish; however, Alternatives 2 and 3 would provide additional fisheries and water quality

benefits. Table 5-5 below summarizes the expected major benefits to salmonids and water quality for all five alternatives in this EIS/EIR as compared to existing conditions.

Table 5-5. Summary of Major Long-term Benefits for Salmonid Restoration and Water Quality

Major long-term benefits of alternatives for water quality and salmonids as compared to existing conditions (baseline)	Alternative 1	Alternatives 2 and 3	Alternative 4	Alternative 5
Water Quality Benefits				
River no longer exceeds OR and CA water temperature, nutrient, dissolved oxygen, pH, and chlorophyll-a TMDL allocations (may not occur by 2061), improving water quality basin wide	X ¹	X	X	X
Accelerates when river no longer exceeds OR and CA water temperature, nutrient, dissolved oxygen, pH, and chlorophyll-a TMDL allocations through the KBRA Fisheries Restoration Plan, improving water quality basin wide		X		
Largely eliminates in 2020 elevated late summer/fall water temperatures in and below the Hydroelectric Reach by removing the largest reservoirs		X		X
Largely eliminates 2020 dissolved oxygen and pH problems produced in reservoirs in the Hydroelectric Reach and transported downstream		X		X
Largely eliminates in 2020 algal toxins produced in the Hydroelectric Reach and transported downstream ³		X		X
Salmonid Benefits				
Iron Gate hatchery smolt production as mitigation for 16 miles of habitat loss would continue	X		X	
Expands access to at least 420 miles of anadromous salmonid habitat and associated smolt production above Iron Gate Dam and development of diverse life histories		X	X	X
Anadromous fish would access low gradient historical habitat of critical importance to spawning and rearing under Copco 1 and Iron Gate Reservoirs		X		X
Provides fish with access to thermal refuge areas that are buffered from future effects from climate change		X	X	X
Provides for natural recruitment of spawning gravel and river processes within and below the Hydroelectric Reach through dam removal		X		Partial ²

Table 5-5. Summary of Major Long-term Benefits for Salmonid Restoration and Water Quality

Major long-term benefits of alternatives for water quality and salmonids as compared to existing conditions (baseline)	Alternative 1	Alternatives 2 and 3	Alternative 4	Alternative 5
Accelerates in 2012 restoration of fish habitat throughout the basin through the KBRA Fisheries Restoration Plan		X		
Accelerates the reintroduction of anadromous fish through the KBRA Fisheries Reintroduction Plan and is consistent with the optimal production from habitat for these species		X		
Expands opportunity to create springtime flushing flows (KBRA Environmental Water Program) and to increase flow variability and bed movement (with dam removal), which reduce juvenile salmon disease below the Hydroelectric Reach		X		Partial
Provides opportunity to reduce juvenile salmon disease by allowing volitional fish passage through the Hydroelectric Reach and decreasing crowding of adult salmon/carcasses		X	X	X
KBRA funding would increase habitat restoration funding, coordination, and monitoring in the Klamath River watershed.		X		
Improves survival of smolts emigrating from tributaries downstream from Iron Gate Dam, such as the Scott and Shasta rivers, where extensive investment in restoration is underway and continuing		X	Partial	Partial
Provides volitional fish passage through the Hydroelectric Reach		X	X	X
Provides optimal efficiency beginning in 2020 of upstream and downstream salmonid migration through the Hydroelectric Reach by creating a free-flowing river		X		
Accelerates the effective use of the Upper Basin by salmonids through the KBRA Fisheries Reintroduction and Management Plan		X		
Improves base flows for salmonids, particularly in drought years, through KBRA Water Resources Program		X		
Eliminates adverse effects of hydroelectric peaking and stranding of fish in the Hydroelectric Reach		X	Partial	X
Eliminates entrainment mortality of resident fish		X	X	X

Table 5-5. Summary of Major Long-term Benefits for Salmonid Restoration and Water Quality

Major long-term benefits of alternatives for water quality and salmonids as compared to existing conditions (baseline)	Alternative 1	Alternatives 2 and 3	Alternative 4	Alternative 5
Reduces concentration of myxospores associated with carcasses accumulating below hatchery facilities, thus reducing disease		X		X

¹“X” means the alternative provides this benefit.

²“Partial” means the alternative provides only some of the benefit.

³ Periphyton are algae that grow attached to rocks and other substrates on a riverbed. Although sometime these species cause nuisance conditions, they are rarely considered toxic. Increased non-toxic periphyton biomass would not lead to increases in algal toxins in the Klamath River. Blooms of phytoplankton (suspended algae) occurring in the calm, lake-like waters are responsible for the production of algal toxins, such as microcystin, in the Klamath River downstream from Iron Gate Dam. Noxious phytoplankton would not thrive in the free flowing river following dam removal.

All action alternatives would provide access to at least 420 miles of historical habitat above Iron Gate Dam for anadromous fish. Additionally under Alternatives 2 and 3, anadromous fish would access low gradient historical habitat of critical importance to spawning and rearing under Copco 1 and Iron Gate Reservoirs. Consequently, the size and diversity of these populations would increase. Removing all Four Facilities would provide for a free-flowing river below Keno dam and would optimize the efficiency of fish migration to and from the Upper Basin as well as through the entire Hydroelectric Reach. In addition, fish would gain access to cold water springs in the Hydroelectric Reach and the Upper Basin, offering improved winter growth opportunities for rearing and some protection against future changes associated with climate change. The entire river from Keno Dam to the Pacific Ocean would become a well-connected, free-flowing river and would provide new fish habitat in the Hydroelectric Reach. Dam removal would maximize the recruitment of gravel within and below the Hydroelectric Reach, which would benefit fish spawning and rearing. Additionally, Alternatives 2 and 3 would create a more natural flow pattern and more bedload transport. The occurrence of juvenile salmon fish disease is anticipated to be reduced as a result of changes in the overall dispersal of adult salmon carcasses, increases in bedload and sediment transport, and reductions in food resources for the intermediate fish disease host. While there is some uncertainty associated with the cycle of disease in juvenile salmon, a reduction in fish disease is likely and this would create better conditions for fish migration, rearing, and spawning. These alternatives would likely eliminate concentrations of carcasses and disease issues associated with Iron Gate Hatchery. Similarly to Alternative 5, the adverse effects of peaking and entrainment into hydroelectric facilities would also be eliminated. Disease risks to resident fish would be low and the establishment of a disease hot spot for *C. shasta* above the current location of Iron Gate Dam would be unlikely. Also, Alternatives 2 and 3 include implementation of all Interim Measures funded by PacifiCorp for the period 2012 through 2020 to improve fish habitat, water quality, and to fund monitoring and critical research.

Similarly to Alternative 5, the release of sediments stored behind Copco 1 and Iron Gate dams would have negative impacts on fish and water quality in the short term (< 2 years) but would provide longer term benefits in the form of increased habitat complexity and increased movement of larger sediment substrate along the river bed (bedload transport), reductions in fish disease, and the nearly complete elimination of toxic algal blooms in the Hydroelectric Reach and downstream. Some chemicals are present in reservoir sediments but at concentrations below critical screening levels for freshwater and marine disposal and do not preclude sediment release downstream.

Alternatives 2 and 3 would eliminate the recreational benefits of project reservoirs such as fishing and some white water recreation opportunities related to peaking flows in the Hydroelectric Reach; however partial and full facilities removal would create new recreational benefits along the Hydroelectric Reach including additional river access and rafting opportunities in the bypassed reaches (the significance of these effects is analyzed in Section 3.20). Because of the elimination of the reservoirs and changes to recreational amenities, Alternatives 2 and 3 would decrease the value of properties with access to or views of the reservoirs. Alternatives 2 and 3 eliminate all hydropower production from the Four Facilities beginning in 2020.

Implementation of KBRA projects and programs under Alternatives 2 and 3 would accelerate basin-wide habitat restoration for fish and accelerate improvement of basin-wide water quality. In the Upper Basin, the KBRA would support water quality improvements in Upper Klamath Lake and Keno Reach, which would benefit migrating salmon and steelhead populations and resident sucker populations in Upper Klamath Lake. The KBRA Fisheries Reintroduction and Management Plans could have direct benefits for salmon by accelerating their reintroduction to the Upper Basin and by providing for fish population monitoring to optimize adaptive management of restoration activities.

Within six months of an Affirmative Determination by the Secretary of the Interior, PacifiCorp would propose a post Iron Gate Dam Mitigation Hatchery Plan that would ensure hatchery mitigation goals are met for eight years following dam removal. After eight years, continued hatchery operations would depend largely on: 1) realized and projected benefits of restored access to additional habitat above the current location of IGD; 2) the success of habitat restoration efforts through the KBRA; and 3) the success of the reintroduction program identified in the KBRA.

Following dam removal seasonal trap and haul operations, primarily for fall-run Chinook salmon may occur around Keno Dam until water quality conditions are sufficiently improved. A variety of release and rearing strategies would be utilized to optimize success; however, the KBRA does not contain specifics on what those strategies might include.

Effects downstream from Iron Gate Dam would include increased production of Chinook salmon due to more favorable flows associated with KBRA and improved habitat condition. In particular, these alternatives would also improve survival of smolts

emigrating from downstream tributaries, such as the Scott and Shasta rivers, due to improved Klamath River flows and disease conditions. Restoration of runs in these two tributaries is the goal of extensive restoration programs.

Both Alternatives 2 and 3 fulfill three key criteria described in the Purpose and Need (Sections ES.3 and 1.5.2.1):

- Establishes a free-flowing condition on the Klamath River from the Keno Dam (River Mile 240) to the Pacific Ocean.
- Allows for full volitional fish passage from the Upper Basin to the Lower Basin of the Klamath River.
- Leads to implementation of KBRA.

Alternatives 2 and 3 have effectively the same in-river effects (i.e. fisheries, habitat, or water quality); any differences between these alternatives are related to societal aspects (scenic, economic, or recreation), as described in Section 5.7.6.

5.7.6 Comparing Alternatives 2 and 3

There are many similarities in the benefits and potential impacts of Alternatives 2 and 3. The main difference between the alternatives is that Alternative 3 would leave some ancillary structures in place, such as powerhouse buildings, pipelines, and penstocks, but both alternatives would create a free-flowing river from Keno Dam to the Pacific Ocean and eliminate any passage barriers to fish on the main stem Klamath River.

Given the fact that fewer structures would be removed under Alternative 3 compared to Alternative 2, there would be fewer short-term environmental impacts associated with construction activities and the use of heavy equipment. Thus, impacts related to the release of greenhouse gases, noise, and ground and land disturbance would be diminished and there would be less likelihood of displacing cultural resources or human remains (impacts to Cultural Resources are analyzed in Section 3.13). However, leaving various ancillary structures in place has the potential to interfere with wildlife movement, aesthetic quality, public safety, and would require some level of long-term maintenance.

Table 5-6 (also Executive Summary, Table ES-7) below compares the effect of Alternative 2 and 3 for all resource categories in this EIS/EIR.

Table 5-6. Detailed Comparison of Alternative 2 and Alternative 3

Resource Category:	Alternative 2 (Alt 2) - Full Facilities Removal	Alternative 3 (Alt 3) - Partial Facilities Removal
<i>Water Quality</i> (Section 3.2)	Both Alt 2 and Alt 3 result in a sediment release from reservoir drawdown which will have similar short-term water quality impacts. In the long term, both Alt 2 and Alt 3 would result in increased spring time water temperatures and changes in daily variation in water temperature. These changes would mean that water temperature patterns in the Klamath River would be restored to normal pre-dam conditions.	

Table 5-6. Detailed Comparison of Alternative 2 and Alternative 3

Resource Category:	Alternative 2 (Alt 2) - Full Facilities Removal	Alternative 3 (Alt 3) - Partial Facilities Removal
Aquatic Resources (Section 3.3)	Both Alt 2 and Alt 3 result in a sediment release from the drawdown of the reservoir which will have similar short-term aquatic resource impacts. In the long term, the increase in the total amount of habitat, reestablishment of bedload sediment transport, reduced transmission of disease, and the improvements in water quality condition will benefit aquatic resources.	
Algae (Section 3.4)	Both Alt 2 and Alt 3 result in increased spring time water temperatures and change daily variation in water temperature. These changes would mean that water temperature patterns in the Klamath River Hydroelectric Reach would be restored to more natural conditions. Similarly the dominant algae would shift from noxious, and at times toxic, lake algae to algae found in moving water.	
Terrestrial Resources (Section 3.5)	Short-term construction impacts to terrestrial resources from Alt 2 maybe higher due to effects from more truck trips and reduction in bat habitat.	Reduced impacts to terrestrial plants and wildlife through reduced construction truck trips. Retained structures for use as a bat habitat.
Flood Hydrology (Section 3.6)	Both Alt 2 and Alt 3 result in a small increase in the peak 100 year flood and change in flood timing. However with mitigation this impact is less than significant.	
Ground Water (Section 3.7)	The dam removal and drawdown described in both Alt 2 and Alt 3 have a decline in the water table surrounding the reservoirs potentially affecting adjacent wells. However with mitigation this impact is less than significant.	
Water Rights/Water Supply (Section 3.8)	Both Alt 2 and Alt 3 result in a sediment release which has a similar very slight impact on water supply in-takes located in the Klamath River downstream from Iron Gate Dam. However with mitigation this impact is less than significant. Removal of the Four Facilities would also require the relocation of the City of Yreka's water supply pipeline. The programmatic analysis of this action showed that design measures incorporated into the project description reduce the potential effects of this action to a less than significant level. Additional environmental compliance will be required for the pipeline relocation.	
Air Quality (Section 3.9)	Greater emissions from short-term construction activities.	Reduced VOC, NOx, CO, SO2, PM10 and PM2.5 emissions due to shorter duration construction activities.
Greenhouse Gases/Climate Change (Section 3.10)	Greater emissions from short-term construction activities.	Short-term reduction in greenhouse gas emissions due to reduced construction activities.
Geology, Soils, and Geologic Hazards (Section 3.11)	The dam removal and drawdown described in both Alt 2 and Alt 3 could cause instability surrounding the reservoirs. However with mitigation this impact is less than significant.	
Tribal Trust (Section 3.12)	Both Alt 2 and Alt 3 result in benefits to aquatic resources and water quality which benefit Indian Trust Assets.	
Cultural/Historic Resources (Section 3.13)	Greater disturbance to archaeological and historic sites given wider and deeper APE footprint. No retention of historic structures.	Reduced disturbance to archaeological and historic sites given less aerial extent of excavation. Some historic structures at Copco 1 (built in 1918) are retained.

Table 5-6. Detailed Comparison of Alternative 2 and Alternative 3

Resource Category:	Alternative 2 (Alt 2) - Full Facilities Removal	Alternative 3 (Alt 3) - Partial Facilities Removal
Land Use, Agricultural, and Forest Resources (Section 3.14)	Slightly more open space for public use through removal of all facilities; however buried facilities may have some associated access restrictions.	Slightly less open space for public use; retained facilities will be fenced off from public use limiting access to some additional areas.
Socioeconomics (Section 3.15)	<p>Fisheries: Improvements to commercial, recreational and tribal fisheries due to habitat expansion and improvement.</p> <p>Community economic impacts (employment, labor income, output): Positive short- and medium-term impacts due to construction, mitigation and KBRA expenditures. Some long-term negative impacts due to reduced expenditures for reservoir and whitewater recreation and dam operations and maintenance. Some long-term positive impacts due to increased expenditures for commercial and recreational fisheries, irrigated agriculture, and refuge recreation.</p> <p>Tribes: Improvements to tribal fisheries and to cultural practices involving fish or water contact.</p> <p>Costs: Most probable estimate of construction and mitigation costs (2020 dollars) = \$292 million. Costs to be divided between PacifiCorp ratepayers (\$200 million) and State of California. KBRA is connected action which will require Federal funding.</p>	<p>Fisheries: Same as Alt 2.</p> <p>Community economic impacts (employment, labor income, output): Same as Alt 2</p> <p>Tribes: Same as Alt 2.</p> <p>Costs: Most probable estimate of construction, life cycle and mitigation costs (2020 dollars) = \$247 million. Life cycle costs pertain to perpetual maintenance and security for appurtenant facilities that are not removed. Costs to be divided between PacifiCorp ratepayers (\$200 million) and State of California. KBRA costs are the same as Alt 2.</p>
Environmental Justice (Section 3.16)	Greater traffic, noise, and vibration could disproportionately effect tribal communities.	Reduced traffic, noise, and vibration could reduce disproportionate effects.
Population & Housing (Section 3.17)	The availability of housing is slightly reduced during construction. However because Alt 2 and Alt 3 have identical peak worker totals the effects are similar.	
Public Utilities (Section 3.18)	Higher volume of construction waste for disposal which would result in greater effects on area landfills.	Lower volume of construction waste for disposal which would result in reduced effects on area landfills.

Table 5-6. Detailed Comparison of Alternative 2 and Alternative 3

Resource Category:	Alternative 2 (Alt 2) - Full Facilities Removal	Alternative 3 (Alt 3) - Partial Facilities Removal
Public Safety (Section 3.18)	Slightly more short-term public safety effects associated with greater traffic. No retained above ground structures improves public safety in the long term.	Reduced traffic would reduce the public safety effects from short-term construction traffic. Under Alt 3 in the long term, there is the risk that facilities that were secured in place could cause an attractive nuisance and public safety effects. Resolving an attractive nuisance issue would fall to the entity ultimately responsible for management of those lands.
Scenic Quality (Section 3.19)	Removal of all structures could improve scenery however some historic properties provide positive scenery attributes.	Retaining some structures could conflict with the surrounding terrain, however some historic properties provide positive scenery* attributes.
Recreation (Section 3.20)	Removal of JC Boyle dam will permanently reduce the number of days with acceptable flows for whitewater boating at Hell's Corner Reach. Both Alt 2 and Alt 3 result in the elimination of reservoir related recreation.	
Toxic/ Hazardous Materials (Section 3.21)	Both Alt 2 and Alt 3 require disposal of a similar amount of hazardous materials.	
Traffic and Transportation (Section 3.22)	Greater traffic and road wear generation.	Reduced traffic and road wear generation due to reduced construction activities
Noise and Vibration (Section 3.23)	Greater noise and vibration generation.	Reduced noise and vibration generation due to reduced construction activities
Color Code Description Key	Less preferred condition for this resource category	Preferred condition for this resource category

5.8 NEPA Environmentally Preferable and Preferred Alternative

5.8.1 NEPA Environmentally Preferable Alternative

NEPA requires that DOI identify the alternative or alternatives that are environmentally preferable in the Record of Decision (ROD) (40 CFR Part 1505.2(b)). The environmentally preferable alternative generally refers to the alternative that would result in the fewest adverse effects to the biological and physical environment. It is also the alternative that would best protect, preserve, and enhance historic, cultural, and natural resources. Although this environmentally preferable alternative must be identified in the ROD, it need not be selected for implementation.

5.8.2 Preferred Alternative

Both Alternative 2 and Alternative 3 include removal of the Four Facilities and implementation of KBRA and both alternatives more fully meet the Purpose and Need (Sections ES.3 and 1.5.2.1). Some key benefits provided by implementation of Alternative 2 and Alternative 3 include (for a full discussion of the Alternatives, see Chapter 3):

- Provides optimal anadromous fish passage to and from at least 420 miles of historical habitat above Iron Gate Dam by creating a free flowing river in the Hydroelectric Reach in 2020
- Anadromous fish would access low gradient historical habitat of critical importance to spawning and rearing under Copco 1 and Iron Gate Reservoirs
- Provides for natural recruitment of spawning gravel and river processes within and below the Hydroelectric Reach through dam removal
- Largely eliminates in 2020 elevated late summer/fall water temperatures in and below the Hydroelectric Reach by removing the largest reservoirs
- Largely eliminates 2020 dissolved oxygen and pH problems produced in reservoirs in the Hydroelectric Reach and transported downstream
- Largely eliminates in 2020 algal toxins produced in the Hydroelectric Reach and transported downstream
- Reduces concentration of myxospores associated with carcasses accumulating below hatchery facilities, thus reducing disease

Removal of the Four Facilities and implementation of KBRA are important components of a durable, long-term solution for local communities and tribes regarding the development, administration, allocation, and advancement of water and native fishery resources of the Klamath Basins. Alternative 2 and Alternative 3 provide a greater opportunity for expanding restoration of salmonids, which, over time would improve harvest opportunities of salmonids, and when compared to the other alternatives, resolve more societal hardships and conflicts that result from over-allocation of scarce natural resources.

Although Alternative 2 and Alternative 3 are similar, Alternative 2 would remove nearly all structures associated with the Four Facilities, while Alternative 3 would allow some structures to remain. By leaving no structures along the shore of the Klamath River, Alternative 2 leads to positive permanent changes in the human environment such as improvements to scenic quality, less long-term maintenance by land-management agencies, and is more protective of public safety. For these reasons Alternative 2 is the preferred alternative.

5.9 CEQA Environmentally Superior Alternative

Section 15126.6(e)(2) of the CEQA Guidelines requires agencies to identify the environmentally superior alternative in a Draft EIR. If the No Project Alternative is the

environmentally superior alternative, an additional environmentally superior alternative must be identified among the other alternatives.

CDFG has identified Alternative 3 (Partial Facilities Removal of Four Dams) as the environmentally superior alternative. All of the alternatives evaluated in the EIS/EIR, including for the No Action/No Project Alternative, have significant unavoidable environmental impacts as identified in Section 5.5. Alternative 2 (Full Facilities Removal of Four Dams, the Proposed Action), Alternative 3, and Alternative 5 (Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate) would have the most short-term significant and unavoidable impacts among the alternatives. These impacts would largely be limited to the time frame of direct dam deconstruction actions and sediment release. After dam deconstruction, impacts would include the loss of reservoir recreation and local economic impacts. Alternatives 2, 3, and 5 would significantly improve water temperature, dissolved oxygen, and algal toxins for aquatic resources and reduce the incidence of fish disease in juvenile salmon by removing the two largest reservoirs—Copco I and Iron Gate. Alternatives 4 and 5 would maintain some power production and recreational benefits thereby reducing local economic impacts.

Although the No Action/No Project Alternative will have no change from existing conditions resulting from construction, this alternative is not the environmentally superior alternative when compared to the Proposed Action, which is intended to improve environmental conditions. Alternative 3 is the environmentally superior alternative when compared with the Proposed Action (Alternative 2) because it would:

- Reduce the air quality impacts from emissions of volatile organic compounds (VOCs), nitrogen oxides (NO_x), carbon monoxide (CO), sulfur dioxide (SO₂), particulate matter < 10 microns (PM₁₀), and particulate matter < 2.5 microns (PM_{2.5}) from reduced construction activities;
- Reduce the contribution to greenhouse gas emissions from reduced construction activities;
- Reduce noise and vibration from reduced construction activities;
- Reduce impacts to terrestrial plants and wildlife from fewer truck trips;
- Reduce disturbance to archaeological and historic sites from fewer truck trips;
- Retain structures for roosting bats; and
- Retain some historically significant structures at the Four Facilities.

Alternative 3 would provide similar long-term benefits when compared with Alternative 2, but would reduce some short-term and long-term impacts because it involves less construction. In summary, Alternative 3 is considered the environmentally superior alternative among all the alternatives because it provides long-term beneficial environmental effects, while reducing some of the short-term significant effects of the Proposed Action (Alternative 2).

5.10 Controversies and Issues Raised by Agencies and the Public

CEQA requires disclosure of the controversial project issues raised by agencies and the public. Table 5-7 (also Executive Summary, Table ES-8) presents a summary of some of the controversial issues and the timeline or process in which they will be addressed, or the document in which they are addressed. The issues were identified during the scoping period and in other forums for public involvement. These are opinions and issues raised by agencies and members of the public and do not necessarily represent the position of the Lead Agencies. Additionally, Table 5-7 is not a summary of findings or determinations from the analysis in this EIS/EIR. See the Scoping Report (located online at: <http://klamathrestoration.gov/>) for further information on issues identified by agencies and the public during the public scoping process (DOI 2010).

Table 5-7. Summary of Controversies and Issues Raised by Agencies and the Public

Issue	Summary of Issue	Timeline for Addressing or Document/Section Addressing Issue
Loss of Renewable Power Supply	Loss of the Klamath Hydroelectric Project will result in the loss of renewable power. The specific makeup of new power supplies is not certain and may come from non-renewable sources.	Greenhouse Gases/Global Climate Change (3.10.4.3) Public Health and Safety, Utilities and Public Services, Solid Waste, Power (Section 3.18.4.3)
Regional Economic Impacts	Loss of the Klamath Hydroelectric Project, lost power generation, and impacts to the local real estate market will negatively and disproportionately affect resource-based economies of local communities, many of which are struggling economically.	Socioeconomics (Section 3.15.4.3)
Sediment Impacts from Dam Removal	Sediment release during dam removal will have significant and deleterious effects on the aquatic environment from Iron Gate Dam to the Pacific Ocean during the period of dam removal.	Water Quality (Section 3.2.4.3) Aquatic Resources (Section 3.4.3) Appendix C
Historic Anadromous Fish Distribution in the Upper Klamath Basin	Dam removal would open large areas of the Upper Klamath Basin watershed to anadromous fish. The historical distribution of anadromous fish above the dams has been questioned.	Chapter 1, Introduction Aquatic Resources (Section 3.3.4.3)

Table 5-7. Summary of Controversies and Issues Raised by Agencies and the Public

Issue	Summary of Issue	Timeline for Addressing or Document/Section Addressing Issue
KBRA Effects	The KBRA may not produce enough social and economic benefits from implementation.	Socioeconomics (Section 3.15.4.3)
KBRA Effects on Environmental Justice and Federal Trust Responsibilities	The KBRA would result in the "termination" of tribal fishing and water rights and the Federal trust responsibilities for those rights and resources, further exacerbating the environmental justice issues associated with declining anadromous fisheries and water quality in the Klamath Basin that have affected tribal practices, health, and cultural traditions	Water Rights and Water Supply (Section 3.8) Indian Trust Assets(Section 3.16)
Loss of Reservoir Environment	Dam removal will result in a loss of the three largest reservoirs, affecting individuals that live on or near the reservoirs and who value the reservoirs' aesthetic and recreational value.	Land Use, Agricultural, and Forest Resources (Section 3.14.4.3) Scenic Quality (Section 3.19.4.3) Recreation (Section 3.20.4.3)
Flood Risk	Dam removal will increase the incidence and magnitude of flooding to downstream communities.	Flood Hydrology (Section 3.6.4.3)
FERC Relicensing	In the event of a Negative Secretarial Determination, PacifiCorp would continue to seek a new license from FERC for operation of the Klamath Hydroelectric Project. The outcome of this process is not known but could be the continued operation of the dams under a new license that includes the agencies' mandatory conditions and prescriptions.	Chapter 2, Proposed Action and Description of Alternatives
Agriculture and Refuge Management contributes to poor water quality in Keno and Upper Klamath Lake	Runoff from agriculture and refuges results in poor water quality in Keno Impoundment/Lake Ewauna and in the mainstem Klamath River. This causes fish stress, disease and mortality. Continued farming and ranching in the Tule Lake National Wildlife Refuge and Lower Klamath Lake National Wildlife Refuge under the KBRA would inhibit fish species reintroduction and survival.	Water Quality (Section 3.2.4.3) Aquatic Resources (Section 3.3.4.3)
Water Quality Conditions in Keno and Upper Klamath Lake would not allow sound fish passage.	Low levels of dissolved oxygen and high water temperatures during certain times of year would adversely affect passage of fish through Keno Impoundment/Lake Ewauna and Upper Klamath Lake.	Water Quality (Section 3.2.4.3) Aquatic Resources (Section 3.3.4.3)
Changes in Types and Amounts of Whitewater Boating	Peaking flows from operation of the hydroelectric project currently allow for commercial whitewater boating in mid- to late-summer.	Socioeconomics (Section 3.15.4.2) Recreation (Section 3.20.4.3)

Table 5-7. Summary of Controversies and Issues Raised by Agencies and the Public

Issue	Summary of Issue	Timeline for Addressing or Document/Section Addressing Issue
Resolution 10-185 of Siskiyou County Board of Supervisors Calling for an Advisory Election with Respect to the Removal of the Dams on the Klamath River on November 2, 2010 (Measure G).	Siskiyou County held an advisory vote on November 2, 2010 regarding dam removal. The ballot asked “ Should the Klamath River Dams (Iron Gate, Copco 1, and Copco 2) and associated hydroelectric facilities be removed – Yes or No?” Of the 25,922 registered voters in the County, 17,206 (66.4%) participated in this vote. The results: Of the 17,206 who voted, 13,566 residents (78.84%) voted No to dam removal, while 3,640 (21.86 %) voted Yes.	While this is not an environmental impact issue and is not specifically addressed as part of this EIS/EIR, the Secretary of the Interior will consider this when making his determination.
"Siskiyou County Water Users Association, Inc. v. California Natural Resources Agency, et al." (Other Defendants are Lester Snow, Secretary of California Natural Resources Agency, Governor Schwarzenegger, DFG, DFG's Director, Humboldt County, Tule Lake Irrigation District, and Westside Improvement District).	This case was originally filed in Sacramento Superior Court on August 16, 2010. The original lawsuit asserted that approval of the KHSA and KBRA violated CEQA, and that DFG is the wrong Lead Agency. The trial court ruled that appellant's claims were time barred because a valid Notice of Determination had been filed, and that a challenge to the Lead Agency designation was not ripe for review. That ruling has been appealed to the Third Appellate District Court of Appeal. Siskiyou County Water Users Association's opening brief was filed on February 15, 2012.	This is not an environmental impact issue and is not specifically addressed as part of this EIS/EIR. It is not yet known how the results of this case may affect the overall project.

¹ CEQA requires disclosure of the controversial project issues raised by agencies and the public. Table 5-7 presents a summary of some of the controversial project issues identified during the scoping period, which are addressed in this EIS/EIR. These are opinions and issues raised by agencies and members of the public and do not necessarily represent the position of the Lead Agencies. Additionally Table 5-7 is not a summary of findings or determinations from the analysis in this EIS/EIR.

Chapter 6

Compliance with Applicable Laws, Policies, and Plans

6.1 Related Laws, Rules, Regulations, Executive Orders, and Other Authorities

This section is a summary of the Federal, tribal, State, and local statutes and regulations that are potentially applicable to the Proposed Action and alternatives presented in this Klamath Facilities Removal Environmental Impact Statement/Environmental Impact Report (EIS/EIR). Some questions remain over the ultimate applicability of local regulations depending on the selection of the Dam Removal Entity (DRE) (responsible for dam deconstruction) or Hydropower Licensee (responsible for taking over the dams and operations). Future environmental analysis and compliance documentation of the Definite Plan and the Klamath Basin Restoration Agreement (KBRA) will specify the applicable regulations with greater certainty once the selection of the DRE or Hydropower Licensee is made.

The removal of the Four Facilities would be subject to multiple Federal and State statutes and local planning regulations. Table 6-1 lists the Federal statutes or requirements, the section of the EIS/EIR it is described in, and any relevant permits or processes required. Table 6-2 provides the regulatory requirements of the State of California and Table 6-3 provides the regulatory requirements of the State of Oregon. Table 6-4 provides the county and city requirements.

Table 6-1. Related Federal Laws, Rules, Regulations, Executive Orders, and Other Authorities

Table 6-4. Local Plans and Policies

Statute	Section with Description	Relevant Permits and Processes
Klamath National Forest Land and Resource Management Plan	The plan guides USFS management of the forest (including recreation goals) and allocates each Wild and Scenic Rivers -designated segment on the Klamath, Scott, and Salmon Rivers within its planning boundary to a management area according to its classification.	EIS/EIR
Redding RMP – covering the Mallard Cove Recreation Area at Copco 1 Reservoir and several parcels crossed by transmission lines at Copco Road and Iron Gate Reservoir.	The RMP focuses on four primary issues: land tenure adjustment, recreation management, access, and forest management (FERC 2007). Recreation opportunities in the Klamath Management Area identified in the RMP include fishing, whitewater boating, hunting, and off-highway vehicle use (BLM 1993)	EIS/EIR
Six Rivers National Forest Land and Resource Management Plan	The plan guides USFS management of the forest (including recreation goals).	EIS/EIR
Siskiyou County Planning and Zoning Ordinance, Article 54 & Title 10, Chapter 10, Flood Damage Prevention	Section 3.6, Flood Hydrology The DRE or Hydropower Licensee will determine if this permit is required.	EIS/EIR, Permit for construction or development within any area of special flood hazard from Public Health and Community Development Department
Siskiyou County Multi-Jurisdictional Hazard Mitigation Plan (HMP)	Section 3.6, Flood Hydrology	EIS/EIR
Siskiyou County Zoning Ordinance, Title 3, Chapter 19, Ground Water Management Planning	Section 3.7, Ground Water	EIS/EIR
Siskiyou County Code of Ordinances Title 10, Chapter 13, Demolition, Deconstruction, Removal, and Reclamation	The DRE or Hydropower Licensee will determine if this permit is required.	Demolition, deconstruction, or removal permit from Public Health and Community Development Department
Siskiyou County - Copco Road Restrictions	The DRE or Hydropower Licensee will coordinate with Siskiyou County to determine the timing and use of Copco Road and required mitigation.	Addressed through application of County Permits and coordination with Siskiyou County
Modoc County General Plan	Section 3.14, Land Use, Agricultural and Forest Resources	EIS/EIR

Washington, DC, Federal Energy Regulatory Commission, Office of Energy Projects, Division of Hydropower Licensing.

Chapter 7

Consultation and Coordination, Document Availability, and Distribution List

This chapter documents the consultation and coordination activities that have occurred during the development of this Klamath Facilities Removal Environmental Impact Statement/ Environmental Impact Report (EIS/EIR). This chapter contains information on where interested parties could view the Draft EIS/EIR and documents the recipients who received a copy of the Draft EIS/EIR or a notice of its availability. For updated information on the Final EIS/EIR, please see Chapter 10.

7.1 Public Involvement

Public involvement is an essential component of the environmental compliance process. The National Environmental Policy Act (NEPA) and California Environmental Quality Act (CEQA) require public participation during the preparation of EISs and EIRs. The following sections describe public involvement opportunities that have occurred or will occur for this EIS/EIR.

7.1.1 Public Scoping

In June 2010, the U.S. Department of the Interior (DOI) published a Notice of Intent in the Federal Register (Vol.75, No. 113, Monday, June 14, 2010) and the California Department of Fish and Game (CDFG) posted a Notice of Preparation with the State Clearinghouse (# 2010062060), announcing the preparation of an EIS/EIR and inviting the public to attend public meetings and submit comments on the project. The Lead Agencies held seven public scoping meetings in a variety of locations around the Klamath Basin. Written and verbal comments were accepted at each meeting. The Lead Agencies also accepted written comments through mail, e-mail, posted on the Web site, and fax, throughout the scoping period of June 14, 2010, through July 21, 2010. Approximately 270 written documents (letters, comment cards, e-mails) and 214 verbal statements were received and reviewed. A Scoping Report that summarizes all comments received through July 21, 2010, was published in September 2010 and is available on the project Web site (<http://klamathrestoration.gov/>).

7.1.2 Public Hearings

The Draft EIS/EIR was released to the public for 100 days of review and comment on Thursday, September 22, 2011. As noted above, a NOA was filed by DOI's Office of Environmental Policy and Compliance in the Federal Register (Federal Register Vol. 76,

No. 184, 58833) on Thursday, September 22, 2011, and an associated NOA was filed by the USEPA in the Federal Register (Federal Register Vol. 76, No. 190, 60822) on Friday September 30, 2011. A Notice of Completion (NOC) was also published in the State Clearinghouse (State Clearinghouse # 2010062060) on the same date, in accordance with CEQA.

During the comment period on the Draft EIS/EIR, the Lead Agencies held six public hearings in California and Oregon. Written and verbal comments were accepted at the public hearings and written comment was accepted throughout the comment period. After receiving numerous requests, the Lead Agencies extended the comment period to allow for additional review and comment. The comment period on the Draft EIS/EIR closed on December 30, 2011, and all comments received to that date have been included in this Final EIS/EIR.

Over 1,400 individual comment submittals were received on the Draft EIS/EIR, including written comments submitted during the comment period and verbal and written comments submitted at the public hearings. Comments were received from Federal, State, tribal, and local governments, private organizations, and members of the public. The comments were considered during the development of this Final EIS/EIR.

7.2 Agency Coordination

Development of this EIS/EIR has involved coordination with a variety of Federal, State, and local agencies. Table 7-1 provides a list of the participating agencies.

Table 7-1. EIS/EIR Participating Agencies¹

Federal Agency/Entity	State Agency/Entity
DOI – Lead Agency	CDFG – Lead Agency
Bureau of Reclamation	State Water Resources Control Board
Bureau of Indian Affairs	North Coast Regional Water Quality Control Board
Bureau of Land Management	State of Oregon
U.S. Geological Survey	Oregon Department of Environmental Quality
National Park Service	Oregon Water Resources Department
U.S. Fish and Wildlife Service	Oregon Department of Fish and Wildlife
U.S. Department of Commerce	
National Oceanic and Atmospheric Administration, Fisheries Service	
U.S. Department of Agriculture	
U.S. Forest Service	
U.S. Environmental Protection Agency	

¹Participating Agencies are the agencies who contributed to the preparation and review of this EIS/EIR.

Key:

DOI = U.S. Department of the Interior

CDFG = California Department of Fish and Game

EIS/EIR = Environmental Impact Statement/Environmental Impact Report

7.2.1 Cooperating Agencies

Cooperating Agencies are Tribes, Federal, State, and local governments (40 CFR Part 1501.6) which have the following:

- Jurisdiction by law, which means authority to approve, veto, or finance all or part of the proposal (40 CFR Part 1508.15); or
- Special expertise, for example, statutory responsibility, agency mission, or related program experience with respect to the proposal or reasonable alternatives (40 CFR Part 1508.26).

Agencies were invited by DOI to be Cooperating Agencies for this EIS/EIR. Table 7-2 presents the list of agencies who were invited as well as those who have accepted the invitation at the time of this document.

Table 7-2. Cooperating Agencies

Type of Agency	Agencies Invited by DOI	Agencies Who Accepted
Tribes	Hoopa Valley Tribe Karuk Tribe The Klamath Tribes Quartz Valley Community Resighini Rancheria Yurok Tribe	Hoopa Valley Tribe Karuk Tribe The Klamath Tribes Quartz Valley Community Resighini Rancheria Yurok Tribe
County and Local Governments	City of Yreka (CA) Curry County (OR) Del Norte County (CA) Humboldt County (CA) Jackson County (OR) Klamath County (OR) Modoc County (CA) Trinity County (CA) Siskiyou County (CA) Siskiyou County Air Pollution Control District (CA) Klamath Water and Power Agency (CA and OR)	Humboldt County (CA) Trinity County (CA) Klamath Water and Power Agency (CA and OR)
State of California Agencies	California State Water Resources Control Board North Coast Regional Water Quality Control Board California Coastal Commission California State Lands Commission North Coast Unified Air Quality Management District California Department of Water Resources Division of Safety of Dams	California State Water Resources Control Board North Coast Regional Water Quality Control Board
State of Oregon Agencies	Oregon Department of Environmental Quality Oregon Department of State Lands Oregon Department of Fish and Wildlife Oregon Water Resources Department	Oregon Department of Environmental Quality Oregon Department of State Lands Oregon Department of Fish and Wildlife

Table 7-2. Cooperating Agencies

Type of Agency	Agencies Invited by DOI	Agencies Who Accepted
		Oregon Water Resources Department
Federal Agencies	U.S. Environmental Protection Agency - Region 9 - Region 10 NOAA Fisheries Service (Southwest Region) U.S. Geological Survey U.S. Forest Service Bureau of Land Management Bureau of Indian Affairs - Pacific Region - Northwest Region U.S. Army Corps of Engineers U.S. Fish and Wildlife Service National Park Service (Pacific West Region) Klamath River Compact Commission	U.S. Environmental Protection Agency ¹ NOAA Fisheries Service (Southwest Region) U.S. Geological Survey U.S. Forest Service Bureau of Land Management Bureau of Indian Affairs ¹ U.S. Fish and Wildlife Service Klamath River Compact Commission

¹Although more than one region has jurisdiction for the project area, both U.S. EPA Regions 9 and 10 and Bureau of Indian Affairs Pacific and Northwest Regions are each participating jointly as one Cooperating Agency.

Abbreviations:

NOAA = National Oceanic and Atmospheric Administration

Cooperating Agencies help to identify issues that need to be addressed in the EIS/EIR, arrange for data collection, analyze data, provide input on alternatives development, and evaluate the impacts of implementing the alternatives. The CEQA Lead Agency is not required to be a Cooperating Agency, and California State agencies do not have to become a Cooperating Agency to fulfill their responsibilities under CEQA.

The Cooperating Agencies participated in three meetings in 2010 and six meetings in 2011 as well as receiving several email updates to share information and provide input in the environmental compliance process, as described in Table 7-3.

Table 7-3. Cooperating Agency Meeting Updates

Date	Location
June, 2010	Ashland, OR
September, 2010	Conference Call
November, 2010	Conference Call
May 18, 2011	Conference Call
June 1, 2011	Conference Call
June 6, 2011	Conference Call
June 15, 2011	Conference Call
June 22, 2011	Conference Call
June 28, 2011	Redding, CA

In addition to these meetings, the Lead Agencies were assisted by the Yurok Tribe, North Coast Regional Water Quality Control Board (NCWQCB), Oregon Department of Environmental Quality (ODEQ), Oregon Department of Fish and Wildlife (ODFW), and Oregon Water Resources Department (OWRD) with technical and policy review of draft sections of the EIS/EIR.

Siskiyou County (CA) and Klamath County (OR) were invited to participate as Cooperating Agencies for this EIS/EIR; however, these entities have not made a formal commitment at the time of this document. The Lead Agencies have responded to multiple requests for meetings to discuss concerns regarding participation, as shown in Table 7-4.

Table 7-4. Meetings with Potential Cooperating Agencies or Non-Government Groups

Date	Entity	Meeting Details
April 1, 2010	Siskiyou County	Board of Supervisors Meeting, Yreka, CA
July 9, 2010	Klamath County	Board of Commissioners Special Meeting, Klamath Falls, OR
July 16, 2010	Hoopa Valley Tribe ¹	Tribal Council Chambers Informal Briefing, Hoopa, CA
September 3, 2010	Hoopa Valley Tribe ¹	Conference Call
September, 2010	Siskiyou County	Siskiyou County Assessor's Office - Mike Mallory
September, 2010	Siskiyou County	Siskiyou County Assessor's Office - Elizabeth Giacomelli
September, 2010	Private Group	Michele Duchi – Lake Shastina Real Estate Center
October, 2010	Siskiyou County	Siskiyou County Assessor's Office - Dan Weale
October, 2010	Siskiyou County	Siskiyou County Public Health & Community Development - Wendy Lucky
October, 2010	Siskiyou County	Siskiyou County Planning Department – Roland Hickel
October, 2010	Private Entity	Ray Singleton – Siskiyou County Broker/Appraiser
October, 2010	Private Entity	Kathy Hayden – Siskiyou County Agent
October, 2010	Private Group	Sharon Grace – Siskiyou County Association of Realtors
February 8, 2011	Siskiyou County	Board of Supervisors Meeting, Yreka, CA
March 3, 2011	Hoopa Valley Tribe ¹	Bureau of Land Management District Office, Medford, OR
October 20, 2011	Local Agency	Copco Fire Protection District, Montague, CA
December 1, 2011	Local Agency	Copco Fire Protection District, Yreka, CA
January 12, 2012	Siskiyou County	Siskiyou County Assessor's Office - Mike Mallory
February 9, 2012	Local Agency	Copco Fire Protection District, Montague, CA
February 15, 2012	Siskiyou County	Siskiyou County Assessor's Office - Mike Mallory
February 15, 2012	Siskiyou County	Briefing on Water Quality and Sediment – Commissioner Cook and Commissioner Kobseff
March 16, 2012	Private Group	Shasta Indian Nation Council – Chairman Roy Hall Jr.
April 10, 2012	Local Agency	Copco Fire Protection District, Montague, CA

¹ Hoopa Valley Tribe became a Cooperating Agency on March 30, 2011.

7.2.2 Reviewing Agencies

The following California State agencies will review the EIS/EIR pursuant to CEQA (State Clearinghouse No. 2010062060):

- California Coastal Commission (CCC)
- California Air Resources Board (CARB)
- Department of Parks and Recreation (California State Parks)
- California Department of Water Resources (CDWR)
- Native American Heritage Commission (NAHC)
- California State Lands Commission (State Lands Commission)
- California Department of Transportation (Caltrans), Districts 1 and 2
- State Water Resources Control Board (SWRCB)
- Regional Water Quality Control Board, Regions 1 and 5
- Integrated Waste Management Board (IWMB)
- California Environmental Protection Agency (CalEPA)
- California Department of Boating and Waterways (CDBW)

7.3 Government-to-Government Consultation

On September 16, 2010, the United States through the Bureau of Indian Affairs (BIA) formally requested government-to-government consultation with the six federally recognized Indian Tribes in the project area: The Klamath Tribes, Quartz Valley Indian Reservation, Karuk Tribe, Hoopa Valley Tribe, Resighini Rancheria, and the Yurok Tribe. Government-to-government consultation was for the Federal trustee to provide tribes with advance notice of an action contemplated and the potential concerns or impacts that may affect their trust resources, and to give the tribes an opportunity to provide input regarding potential concerns or impacts prior to announcing a decision to the public.

Each tribe defined its preferred methods of consultation, the frequency of interactions, and the topics to be discussed with regard to trust resources. The tribes have contributed information for the ongoing scientific studies; two reports on Indian Trust Assets have been produced by BIA for analysis in the EIS/EIR. Tribes have been provided the opportunity to comment on the cultural resources technical report and the Draft EIS/EIR. Tribes acting as Cooperating Agencies for the project have attended the Cooperating Agency meetings and conference calls and have been provided the opportunity to review and comment on the EIS/EIR prior to its release to the public.

Government-to-government consultations were also initiated under Section 106 of the National Historic Preservation Act (NHPA) and Federal Endangered Species Act (ESA), see discussion below. These meetings allowed tribes an opportunity to provide input on the ESA process and content of the draft Biological Opinion (BO), as well as, an opportunity to identify concerns about historic properties, advise on the identification and evaluation of historic properties, including those of traditional religious and cultural

importance, articulate views on potential effects on such properties, and participate in the potential resolution of adverse effects. The six federally recognized Indian Tribes in the project area have been invited to be consulting parties under 36 CFR Part 800. Government-to-government meetings for Section 106 of the NHPA and ESA were held with the Karuk Tribe on December 6, 2011; the Quartz Valley Community on January 9, 2012; the Hoopa Valley Tribe on January 10, 2012; the Yurok Tribe on January 11, 2012; the Resighini Rancheria on January 11, 2012; and the Klamath Tribes on March 7, 2012. A follow-up workshop on ESA was held for Yurok, Karuk, Resighini, and Hoopa Tribes on February 2, 2012 and Quartz Valley Community on February 13, 2012 as well as for the Hoopa Valley Tribe on March 8, 2012. Tribal consultation is ongoing.

While government-to-government consultation is ongoing, Table 7-5 presents a summary of consultations and their subject matter that occurred prior to the release of the Draft EIS/EIR.

Table 7-5. Tribal Consultations

Discussion on the Impacts to ITAs of the Current Operations	
September 28, 2010	Yurok Tribe
September 29, 2010	Resighini Rancheria and Karuk Tribe
September 30, 2010	Quartz Valley Community
October 4, 2010	The Klamath Tribes
November 8, 2010	Hoopa Valley Tribe
Discussion on the Impacts to ITAs of the Alternatives/Comments on the Background Ethnographic Technical Report	
January 24, 2011	The Klamath Tribes
January 25, 2011	Hoopa Valley Tribe and the Resighini Rancheria
January 26, 2011	Yurok Tribal Council

December 6, 2011	Karuk Tribe
January 9, 2012	Quartz Valley Community
January 10, 2012	Hoopa Valley Tribe
January 11, 2012	Yurok Tribe and Resighini Rancheria
March 7, 2012	The Klamath Tribe
Follow-up Discussion on ESA	
February 2, 2012	Yurok, Karuk, Resighini, and Hoopa Tribes
February 13, 2012	Quartz Valley Community
March 7, 2012	Hoopa Valley Tribe (ESA only)

7.4 Non-Government Organization Coordination

The Lead Agencies have encouraged participation of non-government organizations during the environmental review process. DOI has granted the Shasta Nation and the Shasta Indian Nation consulting party status for the Section 106 process pursuant to 36 CFR §§ 800.2(c)(5), 800.3(f). DOI has consulted with, and will continue to consult with, the Shasta Indian Nation through the Section 106 process, which is described below and in Chapter 3.13, Cultural and Historic Resources.

In addition, through [KlamathRestoration.gov](http://klamathrestoration.gov) and the public engagement plan for the Secretarial Determination, DOI invites organizations and groups to request briefings about the project. See <http://klamathrestoration.gov/keep-me-informed>.

7.4.1 Stakeholder Briefings and Technical Workshops

Throughout development of the EIS/EIR and Secretarial Determination scientific studies, the Lead Agencies have held periodic stakeholder briefings and technical workshops that were open to the public. The purpose of the workshops was to gather input, ideas, and information from individual participants for use by the Lead Agencies, and to provide updates on progress, findings, and future plans. Advance notice of briefings and technical workshops was provided on the project Web site, where meeting materials, if applicable, were also posted. Table 7-6 presents a list of the stakeholder briefings and technical workshops that occurred prior to release of the Draft EIS/EIR.

Table 7-6. Stakeholder Briefings and Technical Workshops

Meeting	Date	Location
Stakeholder/Public Workshop	September 28, 2010	Klamath Falls, OR
Stakeholder/Public Workshop	May 6, 2010	Mt. Shasta, CA
Public Information Meeting on Secretarial Determination Science Studies and Technical Report	September 29, 2010	Eureka, CA
Stakeholder/Public Informational Workshop on Water Quality Issues	October 5, 2010	Klamath Falls, OR
Stakeholder/Public Informational Workshop about the fall Chinook salmon production model	October 13, 2010	Yreka, CA
Public Information Meeting on Secretarial Determination Science Studies and Technical Reports	December 9, 2010	Montague, CA (Copco Lake) and Yreka, CA
Public Information Meeting on Secretarial Determination	March 16, 2011	Klamath Falls, OR
Public Information Meeting on Secretarial Determination	June 15, 2011	Orleans, CA

The Lead Agencies presented these briefings for interest groups, affected community members, or others as requested. Information presented at briefings for interested stakeholders is posted on the project Web site.

7.4.2 Briefings on Request

The Klamath Hydroelectric Settlement Agreement (KHSA) created a Technical Coordination Committee (TCC) of non-Federal parties to the KHSA. Appendix A of the KHSA describes the process used by the TCC for meetings and conference calls. At the request of the TCC, Federal team members working on the Secretarial Determination have been invited to provide periodic updates on the process. Several TCC meetings took place in 2010 and 2011. Meeting dates include:

- July 21, 2010
- Sept 9, 2010
- October 6, 2010
- December 14, 2010
- February 23, 2011
- April 6, 2011
- June 16, 2011
- September 8, 2011

The Lead Agencies are prepared to present briefings to interest groups, communities surrounding the project area, local governments, or others as requested and as resources have permitted.

7.5 Endangered Species Act Consultation

The ESA provides for the conservation of federally endangered and threatened species and the ecosystems upon which they depend. Section 7 of the ESA requires Federal agencies to aid in the conservation of listed species and to ensure that the activities of Federal agencies do not jeopardize the continued existence of listed species or adversely modify designated critical habitat. The United States Fish and Wildlife Service (USFWS) and National Oceanic and Atmospheric Administration Fisheries Service (NOAA Fisheries Service) are responsible for administration of the ESA. On January 26, 2011, the DOI notified the USFWS and the National Oceanic and Atmospheric Administration (NOAA) Fisheries Service that, on behalf of the DOI, the Bureau of Reclamation (Reclamation) would be developing a BA in accordance with the ESA to determine if the Proposed Action may adversely affect listed species and/or their critical habitat. From late January to early October, Reclamation informally consulted with NOAA Fisheries Service and USFWS during preparation of the Biological Assessment (BA), including requests for species lists and confirmations, breadth of analysis, topics to be analyzed, and refinement of the action description for consultation. On October 10, 2011, Reclamation transmitted the BO to the USFWS and NOAA Fisheries Service initiating formal consultation under Section 7(a)(2) of the ESA, on the proposed removal of Four Facilities on the Klamath River and the modeled hydrology. No Project actions will be implemented until Reclamation, on behalf of DOI, receives the BO from the Services. In addition, compliance with the California ESA (CESA) may be necessary, depending upon the Dam Removal Entity (DRE).

7.6 Consultation under the Magnuson-Stevens Act

The Magnuson-Stevens Fishery Conservation and Management Act established a management system for national marine and estuarine fishery resources. Pursuant to Section 305(b)(2), all Federal agencies are required to consult with NOAA Fisheries Service regarding any action permitted, funded, or undertaken that may adversely affect essential fish habitat. Effects on habitat managed under any relevant Fishery Management Plans must also be considered. This act pertains primarily to habitat used by species caught in commercial fisheries, which may include habitats in the ocean, estuary and river. DOI is consulting with NOAA Fisheries Service on the effects of the preferred alternative on essential fish habitat. This consultation has occurred in parallel with the ESA consultation (Section 7.5).

7.7 Consultation Pursuant to Section 106 of the NHPA

The NHPA is the primary Federal legislation governing preservation of cultural and historical resources in the United States. The NHPA established a national historic preservation program which encourages the identification and protection of cultural and historic resources. Section 106 of the NHPA is a provision that requires Federal agencies to take into account the effects of their undertakings on historic properties and they must afford the Advisory Council on Historic Preservation (ACHP) an opportunity to comment with regard to the undertaking. Section 106 is implemented by regulations found at 36 CFR Part 800 that guide the consultation process. DOI has elected to integrate compliance with Section 106 of the NHPA through the NEPA process as allowed under 36 CFR Part 800.8(c). DOI has notified the Advisory Council, the California and Oregon State Historical Preservation Office's (SHPO), the federally recognized Indian Tribes identified above, and the two Indian organizations. Consulting parties include Federal agencies involved in the undertaking; the ACHP; SHPO; federally recognized Indian Tribes; local governments; and individuals with a demonstrated interest in the undertaking (including non-federally recognized tribal organizations and members of the public).

On November 23, 2010, DOI, through Reclamation initiated formal Section 106 consultation with California and Oregon SHPOs describing DOI's proposal to remove the four PacifiCorp dams. On June 20, 2011, DOI contacted the California and Oregon SHPOs to discuss DOI's intention of using the NEPA process to comply with the requirements of Section 106 of the NHPA, and sent an official notification letter to the California and Oregon SHPOs on June 23, 2011. DOI also sent the California and Oregon SHPOs a copy of the Cooperating Agency Draft of the cultural resources sections of the Draft EIS/EIR and the draft technical cultural resources report for their internal review.

On March 29, 2011, DOI sought the advice of the ACHP regarding how to comply with Section 106 of the NHPA for the decisionmaking process to evaluate the proposal to remove the four PacifiCorp dams in the Klamath Basin. DOI had a second conversation

with the ACHP to outline an approach to comply with Section 106 of the NHPA on April 8, 2011. On June 24, 2011, DOI officially notified the ACHP of its intention to use the NEPA process to comply with the requirements of Section 106 of the NHPA. In that letter, DOI requested that the ACHP formally participate in the Section 106 consultation process due to the complexities of the Proposed Action which may lead to important questions of policy or interpretation of the NHPA Section 106 regulations and the unique relationships with Indian Tribes which may present issues of concern to those tribes.

On October 19, 2010, the Reclamation sent a letter to the federally recognized Tribes and two non-federally recognized Indian organizations with demonstrated interests in the project area for the KHSA and EIS/EIR initiating Section 106 of the NHPA, and in particular, seeking information regarding traditional cultural properties within the area potentially affected by the proposed removal of the four PacifiCorp dams. Opportunities to comment on historic properties have also been provided during the public scoping and technical meetings, during government-to-government meetings and through other contacts, and during public reviews of the document.

On June 15, 2011, DOI hosted a conference call with the Cooperating Agencies, which includes all of the federally recognized Tribes, to discuss the cultural and tribal resources sections of the Draft EIS/EIR and the draft technical cultural resources report, and to describe DOI's approach to meeting the requirements of Section 106 of the NHPA. During this meeting, DOI answered general questions about the content of cultural and tribal resources sections of the Cooperating Agency Draft of the Draft EIS/EIR and about DOI's Section 106 process. On June 24, 2011, DOI sent an official letter notifying the federally recognized Tribes and two non-federally recognized Indian organizations of its intention to use the NEPA process to comply with the requirements of Section 106 of the NHPA. Tribal consultation for Section 106 was initiated via letters dated October 19, 2010, and June 23, 2011, and continued throughout the NEPA process through correspondence, meetings, government-to-government meetings, emails, and telephone calls. Additional meetings and calls to coordinate on Section 106 were held included: two meetings with California State Historic Preservation Office (SHPO) on February 14, 2012 and March 6, 2012; one meeting with Oregon SHPO on February 28, 2012; one meeting with California and Oregon SHPOs on June 20, 2012; one meeting with the ACHP on March 29, 2012, two meetings with Shasta Indian Nation, a Native American Organization Tribal, on February 9, 2012 (with Copco Fire Protection Agency) and on March 16, 2012; one meeting with the Karuk and Yurok Tribal Historic Preservation Officers, California and Oregon SHPOs, and ACHP on February 21, 2012; and one meeting where all interested parties involved in the Section 106 were invited to attend on June 26, 2012.

Government-to-government meetings were held with the Karuk Tribe on December 6, 2011; the Quartz Valley Community on January 9, 2012; the Hoopa Valley Tribe on January 10, 2012; the Yurok Tribe on January 11, 2012; the Resighini Rancheria on January 11, 2012; and the Klamath Tribes on March 7, 2012 and consultation is ongoing

The Section 106 consultation process among DOI, the California and Oregon SHPOs, the federally recognized Tribes and two non-federally recognized Indian organizations, and any other interested parties will be on-going throughout the EIS/EIR process. The consultation effort with all consulting parties will meet the standards set forth in 36 CFR § 800.8(c)(1)-(4), including additional opportunities to comment on the identification of historic properties, the assessment of effects on such properties, and develop proposed measures that might avoid, minimize, or mitigate any adverse effects on historic properties.

7.8 Environmental Justice – Executive Order 12898

The 1994 Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Population*, requires all Federal agencies to identify and address “disproportionately high and adverse human health or environmental effects” of programs on minority and low-income populations (United States Environmental Protection Agency, 1994).

As noted in Section 7.3, the Lead Agencies have initiated government-to-government consultation with Tribes that may be affected by the project, and have invited all six federally recognized Tribes in the basin to act as Cooperating Agencies for the EIS/EIR. The Lead Agencies held scoping meetings and Draft EIS/EIR hearings for the project at the Karuk Tribe Community Room in Orleans, California, and the Chiloquin Community Center, in Chiloquin, Oregon. Also a Draft EIS/EIR hearing was held at the Yurok Tribe Headquarters in Klamath, California. The Tribes had the opportunity to comment on the Draft EIS/EIR and participate in additional public meetings associated with the release of the Draft EIS/EIR. Upon the Tribes’ request, the Lead Agencies held many separate meetings and calls with Tribes during the preparation of the EIS/EIR to address concerns, to receive input and to share information from tribal agencies and program personnel. Information exchange occurred frequently on technical aspects of flows, biological impacts, water quality, economic impacts, dam deconstruction design, sediment transport and cultural resource protection.

In addition to consultation with the Tribes, the Lead Agencies made efforts to reach other low income or minority communities. These efforts included mailed notifications to property owners along the river and the placement of documents and other information in libraries and on the public Web site. The Lead Agencies held seven public scoping meetings in July 2010 and Draft EIS/EIR meetings in September 2011 throughout the Klamath Basin. Notifications for these meeting were posted on the Web site and in area newspapers. Agency members were available for media interviews during this process.

Section 3.16, Environmental Justice, of this EIS/EIR provides further discussion on Environmental Justice issues.

7.9 Document Availability

This Draft EIS/EIR was made available for review and comment for 100 days with the filing of the Notice of Availability of the EIS on September 22, 2011, with the U.S. Environmental Protection Agency (USEPA) and the Notice of Completion of the EIR with the California State Clearinghouse. The purpose for public review of the Draft EIS/EIR is to receive comments from interested parties on its completeness and adequacy in disclosing the environmental effects of the proposed project. Following the close of the Draft EIS/EIR public review period, the Lead Agencies will prepare and publish a second document containing comments received on the Draft EIS/EIR and responses to the significant environmental points raised in those comments. Together, the Draft EIS/EIR and the responses to comments as well as any changes to the EIS/EIR made in light of comments received constitute a Final EIS/EIR. The DOI is responsible for adopting the EIS as adequate in compliance with the NEPA and CDFG is responsible for certifying that the Final EIR. After the Final EIS/EIR is complete, the Secretary will consider the EIS/EIR among other information when making his decision whether removal of the dams will facilitate fish recovery and is in the best interest of the people of the United States. DOI will complete a record of decision according to NEPA. In the event of an Affirmative Determination, the States of California and Oregon will consider the EIS/EIR when determining if they concur with the Affirmative Determination. The States of California and Oregon will have 60 days after an Affirmative Secretarial Determination to concur with that determination.

Hard copies of this document are available to view at the libraries and Federal and State Agency offices in the Klamath Basin. An electronic version of the document can be viewed on the project Web site listed in Section 7.9.2. Hard copies are also available for purchase, at the expense of the requestor, online via the project Web site listed in Section 7.9.2. To request an electronic copy on CD of the Draft EIS/EIR (accompanied by a hard copy of the Executive Summary), please contact representatives¹ of the Lead Agencies as follows:

Elizabeth Vasquez
Bureau of Reclamation
2800 Cottage Way
Sacramento, CA 95825
Email: klamathsd@usbr.gov
Fax: (916) 978-5055

Gordon Leppig
California Department of Fish and Game
619 Second Street
Eureka, CA 95501
Email: ksdcomments@dfg.ca.gov
Fax: (707) 441-2021

7.9.1 Libraries and Federal and State Agencies

Hard copies of the Draft EIS/EIR are available for public viewing at the libraries and Federal and State Agencies as presented in Table 7-7 and Table 7-8.

¹ Contact information was current as of the fall of 2011. For current project and contact information see www.klamathrestoration.gov.

7.10.2 Businesses, Organizations, and Individual Members of the Public

The Lead Agencies continue to update an extensive project mailing list with over 4,000 businesses, organizations, and property owners along the Klamath River, and members of the public. Those who have attended meetings, provided comments, or expressed an interest in the project have been added to the mailing list. All individuals on the mailing list have received either a copy of the Draft EIS/EIR or notification of its release. The mailing list will continue to be updated throughout the project.

Chapter 8

List of Preparers and Contributors

The following is a list of preparers who contributed to the development of this Final Environmental Impact Statement/Environmental Impact Report.

Table 8-1. Federal Agencies

Preparers	Role in Preparation
Matt Barry	U.S. Fish and Wildlife Service, Project Manager
John Bezdek	Special Advisor to the Chief of Staff
Jerry Bird	U.S. Forest Service, Project Manager
Catherine Cunningham	Bureau of Reclamation, NEPA Compliance
Steve Edmondson	NOAA Fisheries Service, Project Manager
Rhea Graham	Bureau of Reclamation, Project Manager
Blair Greimann	Bureau of Reclamation, Contributor of Reservoir Management Plan and Hydrology, Hydraulics, and Sediment Transport Studies
Thomas Hepler	Bureau of Reclamation, Contributor of Dam Removal Engineering Development and Construction Schedules for Dam Removals
Christine Karas	Bureau of Reclamation, Contracting Officer's Representative for CDM Smith contract
Dennis Lynch	U.S. Geological Survey, Program Manager
Dale Morris	Bureau of Indian Affairs, Project Manager
Laureen Perry	Bureau of Reclamation, NHPA Section 106 Compliance
Renee Snyder	Bureau of Land Management, Project Manager
Elizabeth Vasquez	Bureau of Reclamation, NEPA Document Lead

Key:

NEPA = National Environmental Policy Act

NHPA = National Historic Preservation Act

NOAA = National Oceanic and Atmospheric Administration

Table 8-2. California Department of Fish and Game

Preparers	Role in Preparation
Curt Babcock	CEQA compliance, reviewer of Terrestrial Resources
Diana Chesney	Reviewer of Biology, Fisheries
Gayle Garman	Reviewer of Climate Change, Greenhouse Gas Emissions, Mollusks, Fisheries
Eric Haney	Reviewer of Recreation, Land Use/Real Estate, Aesthetics, Biology – Terrestrial Resources, Population and Housing
Larry Hanson	Reviewer of Biology, Fisheries
Morgan Knechtle	Reviewer of Biology, Fisheries
Karen Kovacs	Reviewer of Biology – Terrestrial Resources, Public Health and Safety, Aesthetics, Traffic and Transportation, Recreation, Land Use/Real Estate
Gordon Leppig	CEQA Document Lead
Matt Myers	Reviewer of Surface Water Hydrology
Mary Olswang	Reviewer of Biology, Fisheries
Mark Pisano	Reviewer of Mollusks, Benthic Macroinvertebrates, Fisheries
Mark Stopher	CEQA compliance and technical review
Jane Vorpapel	Reviewer of Water Quality, Water Rights, Air Quality, Toxic/Hazardous Materials, Solid Waste, Algae

Key:
CEQA = California Environmental Quality Act

Table 8-3. CDM Smith

Preparers	Degree(s)/Years of Experience	Experience and Expertise	Role in Preparation
Hank Boucher, AICP	M.S. Environmental Engineering 36 years experience	Senior Noise Specialist	Noise and Vibration
Carrie Buckman, P.E.	M. Environmental Engineering 12 years experience	Water Resources Engineer	Project Description/ Alternatives, Water Supply/Water Rights
Coral Cavanagh, AICP	M. City Planning 23 years experience	Technical Editor	Technical Editing
Christine Eklund	M.S. Environmental Engineering 5 years of experience	Environmental Engineer	Water Supply/Water Rights
Naomi Fossen	B.S. Civil Engineering 6 years experience	Transportation Engineer	Traffic and Transportation
Selena Gallagher	M.S. Urban and Regional & Environmental Planning 4 years experience	Environmental Planner	Environmental Justice, References, and Technical Editing
Brian Heywood, P.E.	M.S. Civil Engineering 13 years of experience	Senior Water Resources Engineer	Ground Water, Geology and Soils
Julie Hinchcliff	32 years of experience	Word Processor	Word Processing
Michael Izzo	M. City and Regional Planning & Transportation Engineering 7 years experience	Transportation Planner	Traffic and Transportation
Jennifer Jones	M.S. Environmental Science 18 years of experience	Senior Environmental Scientist	Terrestrial Resources
Jeff Key, P.E.	B.S. Civil Engineering 17 years of experience	Senior Transportation Engineer	Traffic and Transportation
Ali Kleyman	M.A. in Environmental Policy and Urban Planning 3 years experience	Environmental Planner	Executive Summary, Introduction, Recreation
Paula Kulis	M.S. Environmental/ Water Resources Engineering 1 year experience	Water Resources Engineer	Population and Housing
Kristen Lemaster, P.E., LEED AP	M.S. Environmental Engineering 10 years experience	Environmental Engineer	Greenhouse Gases and Climate Change
Sami Nall, P.E.	M.S. Environmental Engineering 5 years experience	Environmental Engineer	Compliance with Applicable Laws, Policies and Plans; Consultation and Coordination, Document Availability, and Distribution List
Chris Park, AICP, LEED AP	M.S. City and Regional Planning 5 years experience	Water Resources Planner	Assistant Project Manager, Project Description/ Alternatives

Table 8-3. CDM Smith

Preparers	Degree(s)/Years of Experience	Experience and Expertise	Role in Preparation
Gwen Pelletier	M.S. Environmental Studies 10 years experience	Environmental Scientist	Air Quality, Greenhouse Gases and Climate Change
Stacy Porter	B.A. Environmental Studies 6 years experience	Water Resources Planner	Cumulative Effects
Juan Ramirez	M.S. Environmental Studies 3 years experience	Planner/GIS Analyst	GIS Analysis
Karen Rusk	M.A., English 20 years experience	Technical Editor	Technical Editing
George Siple, QEP	M. Air/Industrial Hygiene 36 years experience	Air Quality Specialist	Air Quality
Cynthia Strong Hibbard	M.S. Environmental Engineering 30 years experience	Senior Environmental Scientist	Greenhouse Gases and Climate Change
Ben Swann, P.G.	B.S. Hydrogeology 26 years experience	Water Resource Management	Project Manager
Asami Tanimoto	M. Eng. Chemical Engineering 5 years experience	Noise Specialist	Noise and Vibration
Juan Tijero	14 years experience	Lead Graphic Designer	Graphic Design
Kassandra Tzou, P.E	M.S. Environmental Engineering 18 years experience	Senior Environmental Engineer	Scenic Quality, Toxic and Hazardous Materials
Stephen Umbertis	M.S City and Regional Planning 4 years experience	Water Resources Planner	Utilities and Public Services, Hydroelectric Power Public, Health and Safety/Solid Waste, Growth Inducing, Land Use and Agriculture
Gina Veronese	M.S. Agricultural and Resource Economics 9 years experience	Resource Economist	Socioeconomics, Environmental Justice
Suzanne Wilkins, AICP	B.S. Business Administration 24 years experience	Water Resources Planner	Hydrology
John Wondolleck	M.S. Zoology 36 years experience	Environmental Management	NEPA/CEQA Document Manager

Key:

AICP = American Institute of Certified Planners

CEQA = California Environmental Quality Act

GIS = Geographic Information Systems

LEED AP = Leadership in Energy and Environmental Design Accredited Professional

NEPA = National Environmental Policy Act

P.E. = Professional Engineer

P.G. = Professional Geologist

QEP = Qualified Environmental Professional

Table 8-4. Cardno/ENTRIX

Preparers	Degree(s)/Years of Experience	Experience and Expertise	Role in Preparation
Karen Klosowski	M. Urban and Regional Planning, 17 years experience	Senior Project Planner	Recreation
Darcy Kremin, AICP	M.A. Urban and Environmental Policy 13 years experience	Senior Environmental Planner	Environmental Justice, Land Use and Agriculture
John Nadolski	M.A. Anthropology 28 years experience	Senior Consultant	Tribal Trust, Cultural Resources, Environmental Justice
Megan Schwartz	M.S. Environmental Science and Management 7 years experience	Senior Project Scientist	Geology and Soils
Larry Wise	M.A. Marine Biology 20 years experience	Fish Ecologist	Aquatic Resources/Fish

Table 8-5. Stillwater Sciences

Preparers	Degree(s)/Years of Experience	Experience and Expertise	Role in Preparation
Peter Fritz Baker	Ph.D. Mathematics 23 years experience	Senior Mathematician	Water Quality
Ethan Bell	M.S. Fisheries Biology 15 years experience	Aquatic Ecologist	Aquatic Resources/Fish
Maia Singer	Ph.D. Environmental Engineering 15 years experience	Senior Scientist/Water Quality Specialist	Water Quality

Table 8-6. River Design Group

Preparers	Degree(s)/Years of Experience	Experience and Expertise	Role in Preparation
Scott Wright, P.E.	M.S. Civil Engineering 17 years experience	Water Resources Engineer	Project Description/ Alternatives
